

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

## PREFACE.

---

THIS book is the result of the experience of the writer in teaching the subject of Applied Mechanics for the last twelve years at the Massachusetts Institute of Technology.

The immediate object of publishing it is, to enable him to dispense with giving to the students a large amount of notes. As, however, it is believed that it may be found useful by others, the following remarks in regard to its general plan are submitted.

The work is essentially a treatise on strength and stability; but, inasmuch as it contains some other matter, it was thought best to call it "Applied Mechanics," notwithstanding the fact that a number of subjects usually included in treatises on applied mechanics are omitted.

It is primarily a text-book; and hence the writer has endeavored to present the different subjects in such a way as seemed to him best for the progress of the class, even though it be at some sacrifice of a logical order of topics. While no attempt has been made at originality, it is believed that some features of the work are quite different from all pre-

vious efforts; and a few of these cases will be referred to, with the reasons for so treating them.

In the discussion upon the definition of "force," the object is, to make plain to the student the modern objections to the usual ways of treating the subject, so that he may have a clear conception of the modern aspect of the question, rather than to support the author's definition, as he is fully aware that this, as well as all others that have been given, is open to objection.

In connection with the treatment of statical couples, it was thought best to present to the student the actual effect of the action of forces on a rigid body, and not to delay this subject until dynamics of rigid bodies is treated, as is usually done.

In the common theory of beams, the author has tried to make plain the assumptions on which it is based. A little more prominence than usual has also been given to the longitudinal shearing of beams.

In that part of the book that relates to the experimental results on strength and elasticity, the writer has endeavored to give the most reliable results, and to emphasize the fact, that, to obtain constants suitable for use in practice, we must deduce them from tests on full-size pieces. This principle of being careful not to apply experimental results to cases very different from those experimented upon, has long been recognized in physics, and therefore needs no justification.

The government reports of tests made at the Watertown Arsenal have been extensively quoted from, as it is believed

---

that they furnish some of our most reliable information on these subjects.

The treatment of the strength of timber will be found to be quite different from what is usually given; but it speaks for itself, and will not be commented upon here.

In the chapter on the "Theory of Elasticity," a combination is made of the methods of Rankine and of Grashof.

In preparing the work, the author has naturally consulted the greater part of the usual literature on these subjects; and, whenever he has drawn from other books, he has endeavored to acknowledge it. He wishes here to acknowledge the assistance furnished him by Professor C. H. Peabody of the Massachusetts Institute of Technology, who has read all the proofs, and has aided him materially in other ways in getting out the work.

GAETANO LANZA.

# APPLIED MECHANICS.

---

## CHAPTER I.

### *COMPOSITION AND RESOLUTION OF FORCES.*

§ 1. **Fundamental Conceptions.** — The fundamental conceptions of Mechanics are Force, Matter, Space, Time, and Motion.

§ 2. **Relativity of Motion.** — The limitations of our natures are such that all our quantitative conceptions are relative. The truth of this statement may be illustrated, in the case of motion, by the fact, that, if we assume the shore as fixed in position, a ship sailing on the ocean is in motion, and a ship moored in the dock is at rest ; whereas, if we assume the sun as our fixed point, both ships are really in motion, as both partake of the motion of the earth. We have, moreover, no means of determining whether any given point is absolutely fixed in position, nor whether any given direction is an absolutely fixed direction. Our only way of determining direction is by means of two points assumed as fixed ; and the straight line joining them, we are accustomed to assume as fixed in direction. Thus, it is very customary to assume the straight line joining the sun with any fixed star as a line fixed in direction ; but if the whole visible universe were in motion, so as to change the absolute direction of this line, we should have no means of recognizing it.

1

§ 3. **Rest and Motion.**—In order to define rest and motion, we have the following; viz., —

When a single point is spoken of as having motion or rest, some other point is always expressed or understood, which is for the time being considered as a fixed point, and some direction is assumed as a fixed direction: and we then say that the first-named point is at rest relatively to the fixed point, when the straight line joining it with the fixed point changes neither in length, nor in direction; whereas it is said to be in motion relatively to the fixed point, when this straight line changes in length, in direction, or in both.

If, on the other hand, we had considered the first-named point as our fixed point, the same conditions would determine whether the second was at rest, or in motion, relatively to the first.

A body is said to be at rest relatively to a given point and to a given direction, when all its points are at rest relatively to this point and this direction.

§ 4. **Velocity.**—When the motion of one point relatively to another, or of one body relatively to another, is such that it describes equal distances in equal times, however small be the parts into which the time is divided, the motion is said to be uniform and the velocity constant.

The velocity, in this case, is the space passed over in a unit of time, and is to be found by dividing the space passed over in any given time by the time; thus, if  $s$  represent the space passed over in time  $t$ , and  $v$  represent the velocity, we shall have

$$v = \frac{s}{t}.$$

When the motion is not uniform, if we divide the time into small parts, and then divide the space passed over in one of these intervals by the time, and then pass to the limit as these intervals of time become shorter, we shall obtain the velocity.

Thus, if  $\Delta s$  represent the space passed over in the interval of time  $\Delta t$ , then we shall have

$$v = \text{limit of } \frac{\Delta s}{\Delta t} \text{ as } \Delta t \text{ diminishes,}$$

or

$$v = \frac{ds}{dt}.$$

§ 5. **Force.** — We shall next attempt to obtain a correct definition of force, or at least of what is called force in mechanics.

It may seem strange that it should be necessary to do this; as it would appear that clear and correct definitions must have been necessary in order to make correct deductions, and therefore that there ought to be no dispute whatever over the meaning of the word *force*. Nevertheless, it is a fact in mechanics, as well as in all those sciences which attempt to deal with the facts and laws of nature, that correct definitions are only gradually developed, and that, starting with very imperfect and often erroneous views of natural laws and phenomena, it is only after these errors have been ascertained and corrected by a long range of observation and experiment, and an increased range of knowledge has been acquired, that exactness and perspicuity can be obtained in the definitions.

Now, this is precisely what has happened in the case of force.

In ancient times *rest* was supposed to be the natural state of bodies; and it was assumed that, in order to make them move, force was necessary, and that even after they had been set in motion their own innate inertia or sluggishness would cause them to come to rest unless they were constantly urged on by the application of some force, the bodies coming to rest whenever the force ceased acting.

It was under the influence of these vague notions that such terms arose as *Force of Inertia*, *Moment of Inertia*, *Vis Viva* or *Living Force*, etc.

A number of these terms are still used in mechanics ; but in all such cases they have been re-defined, such new meanings having been attached to them as will bring them into accord with the more advanced ideas of the present time. Such definitions will be given in the course of this work, as the necessity may arise for the use of the terms.

Moreover, it is to be regretted that there still prevails, to some extent, in the more popular class of scientific literature, a loose usage of such terms, which is very liable to impart erroneous ideas to those whose minds are not clear as to their true meanings.

#### NEWTON'S FIRST LAW OF MOTION.

Ideas becoming more precise, in course of time there was framed Newton's first law of motion ; and this law is as follows :—

A body at rest will remain at rest, and a body in motion will continue to move uniformly and in a straight line, unless and until some external force acts upon it.

The assumed truth of this law was based upon the observed facts of nature ; viz., —

When bodies were seen to be at rest, and from rest passed into a state of motion, it was always possible to assign some cause ; i.e., they had been brought into some new relationship, either with the earth, or with some other body : and to this cause could be assigned the change of state from rest to motion. On the other hand, in the case of bodies in motion, it was seen, that, if a body altered its motion from a uniform rectilinear motion, there was always some such cause that could be assigned. Thus, in the case of a ball thrown from the hand, the attraction of the earth and the resistance of the air soon caused it to come to rest. In the case of a ball rolled along the ground, friction (i.e., the continual contact and collision with the ground) gradually destroyed its motion, and brought it to

rest ; whereas, when such resistances were diminished by rolling it on glass or on the ice, the motion always continued longer : hence it was inferred, that, were these resistances entirely removed, the motion would continue forever.

In accordance with these views, the definition of force usually given was substantially as follows :—

*Force is that which causes, or tends to cause, a body to change its state from rest to motion, from motion to rest, or to change its motion as to direction or speed.*

Under these views, uniform rectilinear motion was recognized as being just as much a condition of equilibrium, or of the action of no force or of balanced forces, as rest ; and the recognition of this one fact upset many false notions, destroyed many incorrect conclusions, and first rendered possible a science of mechanics. Along with the above-stated definition of force is ordinarily given the following proposition ; viz., —

*Forces are proportional to the velocities that they impart, in a unit of time, to the same body.* The reasoning given in support of this proposition is as follows :—

Suppose a body to be moving uniformly and in a straight line, and suppose a force to act upon it for a certain length of time  $t$  in the direction of the body's motion : the effect of the force is to alter the velocity of the body ; and it is only by this alteration of velocity that we recognize the action of the force. Hence, as long as the alteration continues at the same rate, we recognize the same force as acting.

If, therefore,  $f$  represent the amount of velocity which the force would impart in one unit of time, the total increase in the velocity of the body will be  $ft$  ; and, if the force now stop acting, the body will again move uniformly and in the same direction, but with a velocity greater by  $ft$ .

Hence, if we are to measure forces by their effects, it will follow that —

*The velocity which a force will impart to a given (or standard)*

*body in a unit of time is a proper measure of the force.* And we shall have, that two forces, each of which will impart the same velocity to the same body in a unit of time, are equal to each other; and a force which will impart to a given body twice the velocity per unit of time that another force will impart to the same body, is itself twice as great, or, in other words, —

*Forces are proportional to the velocities that they impart, in a unit of time, to the same body.*

#### MODERN CRITICISM OF THE ABOVE.

The scientists and the metaphysicians of the present time are recognizing two other facts not hitherto recognized, and the result is a criticism adverse to the above-stated definition of force. Other definitions have, in consequence, been proposed; but none are free from objection on logical grounds, and at the same time capable of use in mechanics in a quantitative way.

The two facts referred to are the following; viz., —

1°. That all our ideas of space, time, rest, motion, and even of direction, are relative.

2°. That, because two effects are identical, it does not follow that the causes producing those effects are identical.

Hence, in the light of these two facts, it is plain, that, inasmuch as we can only recognize motion as relative, we can only recognize force as acting when at least two bodies are concerned in the transaction; and also that if the forces are simply the causes of the motion in the ordinary popular sense of the word *cause*, we cannot assume, that, when the effects are equal, the causes are in every way identical, although we have, of course, a perfect right to say that they are identical so far as the production of motion is concerned.

I shall now proceed, in the light of the above, to deduce a definition of force, which, although not free from objection, seems as free as any that has been framed.

It is one of the facts of nature, that, when bodies are by any

means brought under certain relations to each other, certain tendencies are developed, which, if not interfered with, will exhibit themselves in the occurrence of certain definite phenomena. What these phenomena are, depends upon the nature of the bodies concerned, and on the relationships into which they are brought.

As an illustration, we know that if an apple is placed at a certain height above the surface of the earth, there is developed between the two bodies a tendency to approach each other; and if there is no interference with this tendency, it exhibits itself in the fall of the apple. If, on the other hand, the apple were hung on the hook of a spring balance in the same position as before, the spring would stretch, and there would be developed a tendency of the spring to make the apple move upwards. This tendency to make the apple move upwards would be just equal to the tendency of the earth and apple to approach each other. This would be expressed by saying that the pull of the spring is just equal and opposite to the weight of the apple.

As other illustrations of these tendencies developed in bodies when placed in certain relations to each other, we have the following cases:—

- (a) When two bodies collide.
- (b) When two substances, coming together, form a chemical union, as sodium and water.
- (c) When the chemical union is entered into only by raising the temperature to some special point.

Any of these tendencies that are developed by bringing about any of these special relationships between bodies might properly be called a force; and the term might properly be, and is, used in the same sense in the mental and moral world, as well as in the physical. In mechanics, however, we have to deal only with the relative motion of bodies; and hence we give the name *force* only to tendencies to change the relative

motion of the bodies concerned ; and this, whether these tendencies are unresisted, and exhibit themselves in the actual occurrence of a change of motion, or whether they are resisted by equal and opposite tendencies, and exhibit themselves in the production of a tensile, compressive, or other stress in the bodies concerned, instead of motion.

#### DEFINITION OF FORCE.

Hence our definition of force, as far as mechanics has to deal with it or is capable of dealing with it, is as follows ; viz., —

*Force is a tendency to change the relative motion of the two bodies between which that tendency exists.*

Indeed, when, as in the illustration given a short time ago, the apple is hung on the hook of a spring balance, there still exists a tendency of the apple and the earth to approach each other ; i.e., they are in the act of trying to approach each other ; and it is this tendency, or *act of trying*, that we call the force of gravitation. In the case cited, this tendency is balanced by an opposite tendency on the part of the spring ; but, were the spring not there, the force of gravitation would cause the apple to fall.

Professor Rankine calls force “an action between two bodies, either causing or tending to cause change in their relative rest or motion ;” and if the *act of trying* can be called an *action*, my definition is equivalent to his.

For the benefit of any one who wishes to follow out the discussions that have lately taken place, I will enumerate the following articles that have been written on the subject : —

(a) “Recent Advances in Physical Science,” by P. G. Tait, Lecture XIV.

(b) Herbert Spencer, “First Principles of Philosophy” (certain portions of the book).

(c) Discussion by Messrs. Spencer and Tait, "Nature," Jan. 2, 9, 16, 1879.

(d) Force and Energy, "Nature," Nov. 25, Dec. 2, 9, 16, 1880.

§ 6. **External Force.**—We thus see, that, in order that a force may be developed, there must be two bodies concerned in the transaction; and we should speak of the force as that developed or existing between the two bodies.

But we may confine our attention wholly to the motion or condition of one of these two bodies; and we may refer its motion either to the other body as a fixed point, or to some body different from either; and then, in speaking of the force, we should speak of it as the force acting on the body under consideration, and call it an external force. It is the tendency of the other body to change the motion of the body under consideration relatively to the point considered as fixed.

§ 7. **Relativity of Force.**—In adopting the above-stated definition of force, we acknowledge our incapacity to deal with it as an absolute quantity; for we have defined it as a tendency to change the relative motion of a pair of bodies. Hence it is only through relative motion that we recognize force; and hence force is relative, as well as motion.

§ 8. **Newton's First Law of Motion.**—In the light of the above discussion, we might express Newton's first law of motion as follows:—

*A body at rest, or in uniform rectilinear motion relatively to a given point assumed as fixed, will continue at rest, or in uniform motion in the same direction, unless and until some external force acts either on the body in question, or on the fixed point, or on the body which furnishes us our fixed direction.* This law is really superfluous, as it has all been embodied in the definition.

§ 9. **Measure of Force.**—We next need some means of comparing forces with each other in magnitude; and, subse-

quently, we need to select one force as our unit force, by means of which to estimate the magnitude of other forces.

Let us suppose a body moving uniformly and in a straight line, relatively to some fixed point; as long as this motion continues, we recognize no unbalanced force acting on it; but, if the motion changes, there must be a tendency to change that motion, or, in other words, an unbalanced force is acting on the body from the instant when it begins to change its motion.

Suppose a body to be moving uniformly, and a force to be applied to it, and to act for a length of time  $t$ , and to be so applied as not to change the direction of motion of the body, but to increase its velocity; the result will be, that the velocity will be increased by equal amounts in equal times, and if  $f$  represent the amount of velocity the force would impart in one unit of time, the total increase in velocity will be  $ft$ . This results merely from the definition of a force; for if the velocity produced in one (a standard) body by a given force is twice as great as that produced by another given force, then is the tendency to produce velocity twice as great in the first case as in the second, or, in other words, the first force is twice as great as the second. Hence —

*Forces are proportional to the velocities which they will impart to a given (or standard) body in a unit of time.*

We may thus, by using one standard body, determine a set of equal forces, and also the proportion between different forces.

**§ 10. Measure of Mass.** — After having determined, as shown, a set of equal (unit) forces, if we apply two of them to different bodies, and let them act for the same length of time on each, and find that the resulting velocities are unequal, these bodies are said to have unequal *masses*; whereas, if the resulting velocities are equal, they are said to have equal *masses*.

Hence we have the following definitions : —

1°. *Equal forces are those which, by acting for equal times on the same or standard body, impart to it equal velocities.*

2°. *Equal masses are those masses to which equal forces will impart equal velocities in equal times.*

§ 11. Suppose two bodies of equal mass moving side by side with the same velocity, and uniformly, let us apply to one of them a force  $F$  in the direction of the body's motion: the effect of this force is to increase the velocity with which the body moves; and if we wish, at the same time, to increase the velocity of the other, so that they will continue to move side by side, it will be necessary to apply an equal force to that also.

We are thus employing a force  $2F$  to impart to the two bodies the required increment of velocity.

If we unite them into one, it still requires a force  $2F$  to impart to the one body resulting from their union the required increment of velocity: hence, if we double the *mass* to which we wish to impart a certain velocity, we must double the force, or, in other words, employ a force which would impart to the first mass alone a velocity double that required. Hence—

*Forces are proportional to the masses to which they will impart the same velocity in the same time.*

§ 12. **Momentum.**—The product obtained by multiplying the number of units of mass in a body by its velocity is called the momentum of the body.

§ 13. **Relation between Force and Momentum.**—The number of units of momentum imparted to a body in a unit of time by a given force, is evidently identical with the number of units of velocity that would be imparted by the same force, in the same time, to a unit mass. Hence—

*Forces are proportional to the momenta (or velocities per unit of mass) which they will generate in a unit of time.*

Hence, if  $F$  represent a force which generates, in a unit of time, a velocity  $f$  in a body whose mass is  $m$ , we shall have

$$F \propto mf;$$

and, inasmuch as the choice of our units is still under our control, we so choose them that

$$F = mf;$$

i.e., the force  $F$  contains as many units of force as  $mf$  contains units of momentum; in other words, —

*The momentum generated in a body in a unit of time by a force acting in the direction of the body's motion, is taken as a measure of the force.*

§ 14. **Statical Measure of Force.** — When the forces are prevented from producing motion by being resisted by equal and opposite forces, as is the case in that part of mechanics known as *Statics*, they must be measured by a direct comparison with other forces. An illustration of this has already been given in the case of an apple hung on the hook of a spring balance. In that case the pull of the spring is equal in magnitude to the weight of the apple: indeed, it is very customary to adopt for forces what is known as the *gravity measure*, in which case we take as our unit the gravitation, or *tendency to fall*, of a given piece of metal, at a given place on the surface of the earth; in other words, its weight at a given place.

The gravity unit may thus be the kilogram, the pound, or the ounce, etc.

It is evident, moreover, from our definition of force, and the subsequent discussion, that whatever we take as our unit of mass, the *statical measure* of a force is proportional to its *dynamical measure*; i.e., the numbers representing the magnitudes of any two forces, in pounds, are proportional to the momenta they will impart to any body in a unit of time.

§ 15. **Gravity Measure of Mass.** — If we assume one pound as our unit of force, one foot as our unit of length, and

one second as our unit of time, the ratio between the number of pounds in any given force and the momentum it will impart to a body on which it acts unresisted for a unit of time, will depend on our unit of mass ; and, as we are still at liberty to fix this as we please, it will be most convenient so to choose it that the above-stated ratio shall be unity, so that there shall be no difference in the measure of a force, whether it is measured statically or dynamically. Now, it is known that a body falling freely under the action of its own weight acquires, every second, a velocity of about thirty-two feet per second : this number is denoted by  $g$ , and varies for different distances from the centre of the earth, as does also the weight of the body.

Now, if  $W$  represent the weight of the body in pounds, and,  $m$  the number of units of mass in its mass, we must have, in order that the statical and dynamical measures may be equal,

$$W = mg.$$

Hence

$$m = \frac{W}{g};$$

i.e., the number of units of mass in a body is obtained by dividing the weight in pounds, by the value of  $g$  at the place where the weight is determined.

The values of  $W$  and of  $g$  vary for different positions, but the value of  $m$  remains always the same for the same body.

#### UNIT OF MASS.

If  $m = 1$ , then  $W = g$ ; or, in words, —

*The weight in pounds of the unit of mass (when the gravity measure is used) is equal to the value of  $g$  in feet per second for the same place.*

§ 16. **Newton's Second Law of Motion.** — Newton's second law of motion is as follows :—

*"Change of momentum is proportional to the impressed moving force, and occurs along the straight line in which the force is impressed"*

Newton states further in his "Principia:—" —

"If any force generate any momentum, a double force will generate a double, a triple force will generate a triple, momentum, whether simultaneously and suddenly, or gradually and successively impressed. And if the body was moving before, this momentum, if in the same direction as the motion, is added; if opposite, is subtracted; or if in an oblique direction, is annexed obliquely, and compounded with it, according to the direction and magnitude of the two."

Part of this law has reference to the proportionality between the force and the momentum imparted to the body; and this has been already embodied in our definition of force, and illustrated in the discussion on the measure of forces.

The other part is properly a law of motion, and may be expressed as follows:—

*If a body have two or more velocities imparted to it simultaneously, it will move so as to preserve them all.*

The proof of this law depends merely upon a proper conception of motion. To illustrate this law when two velocities are imparted simultaneously to a body, let us suppose a man walking on the deck of a moving ship: he then has two motions in relation to the shore, his own and that of the ship.

Suppose him to walk in the direction of motion of the ship at the rate of 10 feet per second, while the ship moves at 25 feet per second relatively to the shore: then his motion in relation to the shore will be  $25 + 10 = 35$  feet per second. If, on the other hand, he is walking in the opposite direction at the same rate, his motion relatively to the shore will be  $25 - 10 = 15$  feet per second.

Suppose a body situated at *A* (Fig. 1) to have two motions imparted to it simultaneously, one of which would carry it to *B*

in one second, and the other to  $C$  in one second; and that it is required to find where it will be at the end of one second, and what path it will have pursued.

Imagine the body to move in obedience to the first alone, during one second: it would thus arrive at  $B$ ; then suppose the second motion to be imparted to the body, instead of the first, it will arrive at the end of the next second at  $D$ , where  $BD$  is equal and parallel to  $AC$ . When the two motions are imparted simultaneously, instead of successively, the same point  $D$  will be reached in one second, instead of two; and by dividing  $AB$  and  $AC$  into the same (any) number of equal parts, we can prove that the body will always be situated at some point of the diagonal  $AD$  of the parallelogram, hence that it moves along  $AD$ . Hence follows the proposition known as the parallelogram of motions.

#### PARALLELOGRAM OF MOTIONS.

*If there be simultaneously impressed on a body two velocities, which would separately be represented by the lines  $AB$  and  $AC$ , the actual velocity will be represented by the line  $AD$ , which is the diagonal of the parallelogram of which  $AB$  and  $AC$  are the adjacent sides.*

§ 17. **Polygon of Motions.** — In all the above cases, the point reached by the body at the end of a second when the two motions take place simultaneously is the same as that which would be reached at the end of two seconds if the motions took place successively; and the path described is the straight line joining the initial position of the body, with its position at the end of one second when the motions are simultaneous.

The same principle applies whatever be the number of velocities that may be imparted to a body simultaneously. Thus, if we suppose the several velocities imparted to be (Fig. 2)  $AB$ ,  $AC$ ,  $AD$ ,  $AE$ , and  $AF$ , and it be required to

determine the resultant velocity, we first let the body move with the velocity  $AB$  for one second; at the end of that second it is found at  $B$ ; then let it move with the velocity  $AC$  only, and at the end of another second it will be found at  $c$ ; then with  $AD$  only, and at the end of the third second it will be found at  $d$ ; at the end of the fourth at  $e$ ; at the end of the fifth at  $f$ . Hence the resultant velocity, when all are imparted simultaneously, is  $Af$ , or the closing side of the polygon.

FIG. 2.

This proposition is known as the polygon of motions.

#### POLYGON OF MOTIONS.

*If there be simultaneously impressed on a body any number of velocities, the resulting velocity will be represented by the closing side of a polygon of which the lines representing the separate velocities form the other sides.*

§ 18. **Characteristics of a Force.**—A force has three characteristics, which, when known, determine it; viz., *Point of Application*, *Direction*, and *Magnitude*. These can be represented by a straight line, whose length is made proportional to the magnitude of the force, whose direction is that of the motion which the force imparts, or tends to impart, and one end of which is the point of application of the force; an arrow-head being usually employed to indicate the direction in which the force acts.

#### § 19. Parallelogram of Forces.

**PROPOSITION.**—*If two forces acting simultaneously at the same point be represented, in point of application, direction, and magnitude, by two adjacent sides of a parallelogram, their resultant will be represented by the diagonal of the parallelogram, drawn from the point of application of the two forces.*

**PROOF.**—In the last part of § 16 was proved the propo-

sition known as the *Parallelogram of Motions*, for the statement of which the reader is referred to the close of that section.

We have also seen that forces are proportional to the velocities which they impart, or tend to impart, in a unit of time, to the same body.

Hence the lines representing the two impressed forces are coincident in direction with, and proportional to, the lines representing the velocities they would impart in a unit of time to the same body; and moreover, since the resultant velocity is represented by the diagonal of the parallelogram drawn with the component velocities as sides, the resultant force must coincide in direction with the resultant velocity, and the length of the line representing the resultant force will bear to the resultant velocity the same ratio that one of the component forces bears to the corresponding velocity. Hence it follows, that the resultant force will be represented by the diagonal of the parallelogram having for sides the two component forces.

#### § 20. Parallelogram of Forces: Algebraic Solution.

PROBLEM. — *Given two forces  $F$  and  $F_1$ , acting at the same point  $A$  (Fig. 3), and inclined to each other at an angle  $\theta$ ; required the magnitude and direction of the resultant force.*

Let  $AC$  represent  $F$ ,  $AB$  represent  $F_1$ , and let angle  $BAC = \theta$ ; then will  $R = AD$  represent in magnitude and direction the resultant force. Also let angle  $DAC = \alpha$ ; then from the triangle  $DAC$  we have

$$AD^2 = AC^2 + CD^2 - 2AC \cdot CD \cos ACD.$$

But

$$ACD = 180^\circ - \theta \quad \therefore \cos ACD = -\cos \theta$$

$$\therefore R^2 = F^2 + F_1^2 + 2FF_1 \cos \theta$$

$$\therefore R = \sqrt{F^2 + F_1^2 + 2FF_1 \cos \theta}.$$

This determines the magnitude of  $R$ . To determine its direction, let angle  $CAD = \alpha$   $\therefore$  angle  $BAD = \theta - \alpha$ , and we shall have from the triangle  $DAC$

$$CD : AD = \sin CAD : \sin ACD,$$

or

$$F_1 : R = \sin \alpha : \sin \theta$$

$$\therefore \sin \alpha = \frac{F_1}{R} \sin \theta,$$

and similarly

$$\sin(\theta - \alpha) = \frac{F}{R} \sin \theta.$$

#### EXAMPLES.

- 1°. Given  $F = 47.34$ ,  $F_1 = 75.46$ ,  $\theta = 73^\circ 14' 21''$ ; find  $R$  and  $\alpha$ .
- 2°. Given  $F = 5.36$ ,  $F_1 = 4.27$ ,  $\theta = 32^\circ 10'$ ; find  $R$  and  $\alpha$ .
- 3°. Given  $F = 42.00$ ,  $F_1 = 31.00$ ,  $\theta = 150^\circ$ ; find  $R$  and  $\alpha$ .
- 4°. Given  $F = 47.00$ ,  $F_1 = 75.00$ ,  $\theta = 253^\circ$ ; find  $R$  and  $\alpha$ .

§ 21. Parallelogram of Forces when  $\theta = 90^\circ$ . — When the two given forces are at right angles to each other, the formulæ become very much simplified, since the parallelogram becomes a rectangle.

From Fig. 4 we at once deduce

FIG. 4.

$$R = \sqrt{F^2 + F_1^2},$$

$$\sin \alpha = \frac{F_1}{R},$$

$$\cos \alpha = \frac{F}{R}.$$

#### EXAMPLES.

- 1°. Given  $F = 3.0$ ,  $F_1 = 5.0$ ; find  $R$  and  $\alpha$ .
- 2°. Given  $F = 3.0$ ,  $F_1 = -5.0$ ; find  $R$  and  $\alpha$ .
- 3°. Given  $F = 5.0$ ,  $F_1 = 12.0$ ; find  $R$  and  $\alpha$ .
- 4°. Given  $F = 23.2$ ,  $F_1 = 21.3$ ; find  $R$  and  $\alpha$ .

§ 22. **Triangle of Forces.**— *If three forces be represented, in magnitude and direction, by the three sides of a triangle taken in order, then, if these forces be simultaneously applied at one point, they will balance each other.*

*Conversely, three forces which, when simultaneously applied at one point, balance each other, can be correctly represented in magnitude and direction by the three sides of a triangle taken in order.*

These propositions, which find a very extensive application, especially in the determination of the stresses in roof and bridge trusses, are proved as follows:—

If we have two forces,  $AC$  and  $AB$  (see Fig. 3), acting at the point  $A$ , their resultant is, as we have already seen,  $AD$ ; and hence a force equal in magnitude and opposite in direction to  $AD$  will balance the two forces  $AC$  and  $AB$ . Now, the sides of the triangle  $ACDA$ , if taken in order, represent in magnitude and direction the force  $AC$ , the force  $CD$  or  $AB$ , and a force equal and opposite to  $AD$ ; and these three forces, if applied at the same point, would balance each other. Hence follows the proposition.

Moreover, we have

$$AC : CD : DA = \sin ADC : \sin CAD : \sin ACD,$$

or

$$F : F_1 : R = \sin(\theta - \alpha) : \sin \alpha : \sin \theta;$$

or each force is, in this case, proportional to the sine of the angle between the other two.

§ 23. **Decomposition of Forces in one Plane.**— It is often convenient to resolve a force into two components, in two given directions in a plane containing the force. Thus, suppose we have the force  $R = AD$  (Fig. 3), and we wish to resolve it into two components acting respectively in the directions  $AC$  and  $AB$ ; i.e., we wish to find two forces acting respectively in these directions, of which  $AD$  shall be the resultant: we

determine these components graphically by drawing a parallelogram, of which  $AD$  shall be the diagonal, and whose sides shall have the directions  $AC$  and  $AB$  respectively. The algebraic values of the magnitudes of the components can be determined by solving the triangle  $ADC$ . In the case when the directions of the components are at right angles to each other, let the force  $R$  (Fig. 5), applied at  $O$ , make an angle  $\alpha$  with  $OX$ . We may, by drawing the rectangle shown in the figure, decompose  $R$  into two components,  $F$  and  $F_i$ , along  $OX$  and  $OY$  respectively; and we shall readily obtain from the figure,

$$F = R \cos \alpha, \quad F_i = R \sin \alpha.$$

#### EXAMPLES.

1°. The force exerted by the steam upon the piston of a steam-engine at the moment when it is in the position shown in the figure is  $AB = 1000$  lbs. The resistance of the guides upon the cross-head  $DE$  is vertical. Determine the force acting along the connecting-rod  $AC$  and the pressure on the guides; also

FIG. 6.

FIG. 7.

resolve the force acting along the connecting-rod into two components, one along, and the other at right angles to, the crank  $OC$ .  
2°. A load of 500 lbs. is placed at the apex  $C$  of the frame  $ACB$ : find the stresses in  $AC$  and  $CB$  respectively.

3°. A load of 4000 lbs. is hung at  $C$ , on the crane  $ABC$ : find the pressure in the boom  $BC$ , and the pull on the tie  $AC$ , where  $BC$  makes an angle of  $60^\circ$  with the horizontal, and  $AC$  an angle of  $15^\circ$ .

FIG. 8.

4°. A force whose magnitude is 7 is resolved into two forces whose magnitudes are 5 and 3: find the angles they make with the given force.

§ 24. Composition of any Number of Forces in One Plane, all applied at the Same Point.

(a) GRAPHICAL SOLUTION. — Let the forces be represented (Fig. 2) by  $AB$ ,  $AC$ ,  $AD$ ,  $AE$ , and  $AF$  respectively. Draw  $Bc \parallel$  and  $= AC$ ,  $cd \parallel$  and  $= AD$ ,  $de \parallel$  and  $= AE$ , and  $ef \parallel$  and  $= AF$ ; then will  $Af$  represent the resultant of the five forces. This solution is to be deduced from § 17 in the same way as § 19 is deduced from § 16.

(b) ALGEBRAIC SOLUTION. — Let the given forces (Fig. 9), of which three are represented in the figure, be  $F$ ,  $F_1$ ,  $F_2$ ,  $F_3$ ,  $F_4$ , etc.; and let the angles made by these forces with the axis  $OX$  be  $\alpha$ ,  $\alpha_1$ ,  $\alpha_2$ ,  $\alpha_3$ ,  $\alpha_4$ , etc., respectively. Resolve each of these forces into two components, in the directions  $OX$  and  $OY$  respectively. We shall obtain for the components along  $OX$

$$OA = F \cos \alpha, \quad OB = F_1 \cos \alpha_1, \quad OC = F_2 \cos \alpha_2, \quad \text{etc.};$$

and for those along  $OY$

$$OA_1 = F \sin \alpha, \quad OB_1 = F_1 \sin \alpha_1, \quad OC_1 = F_2 \sin \alpha_2, \quad \text{etc.}$$

These forces are equivalent to the following two; viz., a force  $F \cos \alpha + F_1 \cos \alpha_1 + F_2 \cos \alpha_2 + F_3 \cos \alpha_3 + \text{etc.}$  along  $OX$ , and a force  $F \sin \alpha + F_1 \sin \alpha_1 + F_2 \sin \alpha_2 + F_3 \sin \alpha_3 + \text{etc.}$  along  $OY$ . The first may be represented by  $\Sigma F \cos \alpha$ , and the second by  $\Sigma F \sin \alpha$ , where  $\Sigma$  stands for *algebraic sum*. There remains only to find the resultant of these two, the magnitude of which is given by the equation

$$R = \sqrt{(\Sigma F \cos \alpha)^2 + (\Sigma F \sin \alpha)^2};$$

FIG. 9.

and, if we denote by  $a_r$  the angle made by the resultant with  $OX$ , we shall have

$$\cos a_r = \frac{\Sigma F \cos a}{R}, \quad \sin a_r = \frac{\Sigma F \sin a}{R}.$$

## EXAMPLES.

1°. Given  $\left\{ \begin{array}{l} F = 47 \\ F_1 = 73 \\ F_2 = 43 \\ F_3 = 23 \end{array} \right. \quad \left\{ \begin{array}{l} a = 21^\circ \\ a_1 = 48^\circ \\ a_2 = 82^\circ \\ a_3 = 112^\circ \end{array} \right. \quad \left. \begin{array}{l} \text{Find the result-} \\ \text{ant force and} \\ \text{its direction.} \end{array} \right.$

## Solution.

| $F$ . | $a$ .       | $\cos a$ . | $\sin a$ . | $F \cos a$ . | $F \sin a$ . |
|-------|-------------|------------|------------|--------------|--------------|
| 47    | $21^\circ$  | 0.93358    | 0.35837    | 43.87826     | 16.84339     |
| 73    | $48^\circ$  | 0.66913    | 0.74315    | 48.84649     | 54.24995     |
| 43    | $82^\circ$  | 0.13917    | 0.99027    | 5.98431      | 42.58161     |
| 23    | $112^\circ$ | -0.37461   | 0.92718    | -8.61603     | 21.32414     |
|       |             |            |            | 90.09303     | 134.99909    |

$$\therefore \Sigma F \cos a = 90.09303, \quad \Sigma F \sin a = 134.99909,$$

$$\therefore R = \sqrt{(\Sigma F \cos a)^2 + (\Sigma F \sin a)^2} = 162.2976.$$

$$\log \Sigma F \cos a = 1.954691$$

$$\log R = 2.210331$$

$$\log \cos a_r = 9.744360$$

$$a_r = 56^\circ 17'.$$

OBSERVATION. — It would be perfectly correct to use the minus sign in extracting the square root, or to call  $R = -162.2976$ ; but then we should have

$$\cos a_r = \frac{90.09303}{-162.2976}, \quad \text{and} \quad \sin a_r = \frac{134.99909}{-162.2976},$$

or

$$a_r = 180^\circ + 56^\circ 17' = 236^\circ 17';$$

a result which, if plotted, would give the same force as when we call

$$R = 162.2976 \quad \text{and} \quad \alpha_r = 56^\circ 17'.$$

Hence, since it is immaterial whether we use the plus or the minus sign in extracting the square root provided the rest of the computation be consistent with it, we shall, for convenience, use always plus.

$$\begin{array}{lll} 2^\circ. & F = 4, & \alpha = 77^\circ, \\ & F_1 = 3, & \alpha_1 = 82^\circ, \\ & F_2 = 10, & \alpha_2 = 163^\circ, \\ & F_3 = 5, & \alpha_3 = 275^\circ. \end{array}$$

$$\begin{array}{lll} 3^\circ. & F = 5, & \alpha = \cos^{-1} \frac{4}{5}, \\ & F_1 = 4, & \alpha_1 = 0, \\ & F_2 = 3, & \alpha_2 = 90^\circ. \end{array}$$

§ 25. **Polygon of Forces.**—If any number of forces be represented in magnitude and direction by the sides of a polygon taken in order, then, if these forces be simultaneously applied at one point, they will balance each other.

Conversely, any number of forces which, when simultaneously applied at one point, balance each other, can be correctly represented in magnitude and direction by the sides of a polygon taken in order.

These propositions are to be deduced from § 24 (a) in the same way as the *triangle of forces* is deduced from the parallelogram of forces.

§ 26. **Composition of Forces all applied at the Same Point, and not confined to One Plane.**—This problem can be solved by the polygon of forces, since there is nothing in the demonstration of that proposition that limits us to a plane rather than to a *gauche* polygon.

The following method, however, enables us to determine algebraic values for the magnitude of the resultant and for its direction.

FIG. 10.

We first assume a system of three rectangular axes,  $OX$ ,  $OY$ , and  $OZ$  (Fig. 10), whose origin is at the common point of the given forces. Now, let  $OE = F$  be one of the given forces. First resolve it into two forces,  $OC$  and  $OD$ , the first of which lies in the  $z$  axis, and the second perpendicular to  $OZ$ , or, as it is usually called, in the  $x$  plane; the plane perpendicular to  $OX$  being the  $x$  plane, and that perpendicular to  $OY$  the  $y$  plane. Then resolve  $OD$  into two components,  $OA$  along  $OX$ , and  $OB$  along  $OY$ . We thus obtain three forces,  $OA$ ,  $OB$ , and  $OC$  respectively, which are equivalent to the single force  $OE$ . These three components are the edges of a rectangular parallelepiped, of which  $OE = F$  is the diagonal.

Let, now,

$$\text{angle } EOX = \alpha, \quad EOY = \beta, \quad \text{and } EOZ = \gamma;$$

and we have, from the right-angled triangles  $EOA$ ,  $EOB$ , and  $EOC$  respectively,

$$OA = F \cos \alpha, \quad OB = F \cos \beta, \quad OC = F \cos \gamma.$$

Moreover,

$$OA^2 + OB^2 = OD^2 \quad \text{and} \quad OD^2 + OC^2 = OE^2$$

$$\therefore OA^2 + OB^2 + OC^2 = OE^2,$$

and by substituting the values of  $OA$ ,  $OB$ , and  $OC$ , given above, we obtain

$$\cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1;$$

a purely geometrical relation existing between the three angles that any line makes with three rectangular co-ordinate axes.

When two of the angles  $\alpha$ ,  $\beta$ , and  $\gamma$  are given, the third can be determined from the above equation.

Resolve, in the same way, each of the given forces into three components, along  $OX$ ,  $OY$ , and  $OZ$  respectively, and we shall thus reduce our entire system of forces to the following three forces:—

- 1°. A single force  $\Sigma F \cos \alpha$  along  $OX$ .
- 2°. A single force  $\Sigma F \cos \beta$  along  $OY$ .
- 3°. A single force  $\Sigma F \cos \gamma$  along  $OZ$ .

We next proceed to find a single resultant for these three forces.

Let (Fig. 11)

$$\begin{aligned} OA &= \Sigma F \cos \alpha \\ OB &= \Sigma F \cos \beta, \\ OC &= \Sigma F \cos \gamma. \end{aligned}$$

FIG. 11.

Compounding  $OA$  and  $OB$ , we find  $OD$  to be their resultant; and this, compounded with  $OC$ , gives  $OE$  as the resultant of the entire system. Moreover,

$$OE^2 = OD^2 + OC^2 = OA^2 + OB^2 + OC^2,$$

or

$$R^2 = (\Sigma F \cos \alpha)^2 + (\Sigma F \cos \beta)^2 + (\Sigma F \cos \gamma)^2$$

$$\therefore R = \sqrt{(\Sigma F \cos \alpha)^2 + (\Sigma F \cos \beta)^2 + (\Sigma F \cos \gamma)^2};$$

and if we let  $EOX = \alpha_r$ ,  $EOY = \beta_r$ , and  $EOZ = \gamma_r$  we shall have

$$\cos \alpha_r = \frac{OA}{OE} = \frac{\Sigma F \cos \alpha}{R}, \quad \cos \beta_r = \frac{\Sigma F \cos \beta}{R}, \quad \text{and} \quad \cos \gamma_r = \frac{\Sigma F \cos \gamma}{R}.$$

This gives us the magnitude and direction of the resultant.

The same observation applies to the sign of the radical for  $R$  as in the case of forces confined to one plane.

## DETERMINATION OF THE THIRD ANGLE FOR ANY ONE FORCE.

When two of the angles  $\alpha$ ,  $\beta$ , and  $\gamma$  are given, the cosine of the third may be determined from the equation, —

$$\cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1;$$

but, as we may use either the plus or the minus sign in extracting the square root, we have no means of knowing which of the two supplementary angles whose cosine has been deduced is to be used.

Thus, suppose  $\alpha = 45^\circ$ ,  $\beta = 60^\circ$ , then

$$\cos \gamma = \pm \sqrt{1 - \frac{1}{2} - \frac{1}{4}} = \pm \frac{1}{2}$$

$$\therefore \gamma = 60^\circ, \text{ or } 120^\circ;$$

but which of the two to use we have no means of deciding.

This indetermination will be more clearly seen from the following geometrical considerations:—

The angle  $\alpha$  (Fig. 12), being given as  $45^\circ$ , locates the line representing the force on a right circular cone, whose axis is  $OX$ , and whose semi-vertical angle is  $AOX = BOX = 45^\circ$ . On the other hand, the statement that  $\beta = 60^\circ$  locates the force on another right circular cone, having  $OY$  for axis, and a semi-vertical angle of  $60^\circ$ ; both cones, of course, having their vertices at  $O$ . Hence, when  $\alpha$  and  $\beta$  are given, we know that the line

FIG. 12.

representing the force is an element of both cones; and this is all that is given.

(a) Now, if the sum of the two given angles is less than  $90^\circ$ , the cones will not intersect, and the data are consequently inconsistent.

(b) If, on the other hand, one of the given angles being greater than  $90^\circ$ , their difference is greater than  $90^\circ$ , the cones will not intersect, and the data are again inconsistent.

(c) If  $\alpha + \beta = 90^\circ$ , the cones are tangent to each other, and  $\gamma = 90^\circ$ .

(d) If  $\alpha + \beta > 90^\circ$ , and  $\alpha - \beta$  or  $\beta - \alpha < 90^\circ$ , the cones intersect, and have two elements in common; and we have no means of determining, without more data, which intersection is intended, this being the indetermination that arises in the algebraic solution.

## EXAMPLES.

1. Given  $\left\{ \begin{array}{lll} F = 63 & \alpha = 53^\circ & \beta = 42^\circ \\ F_1 = 49 & \alpha = 87^\circ & \gamma = 72^\circ \\ F_2 = 2 & \beta = 70^\circ & \gamma = 45^\circ \end{array} \right\}$  Find the magnitude and direction of the resultant.

## Solution.

| $P$ | $\alpha$   | $\beta$    | $\gamma$   | $\cos \alpha$ | $\cos \beta$ | $\cos \gamma$ | $P \cos \alpha$        | $P \cos \beta$        | $P \cos \gamma$        |
|-----|------------|------------|------------|---------------|--------------|---------------|------------------------|-----------------------|------------------------|
| 63  | $53^\circ$ | $42^\circ$ |            | 0.60182       | 0.74314      | 0.29250       | 37.91466               | 46.81782              | 18.42750               |
| 49  | $87^\circ$ |            | $72^\circ$ | 0.05234       | 0.94961      | 0.30902       | 2.56466                | 46.53089              | 15.14198               |

§ 27. Conditions of Equilibrium for Forces applied at a Single Point.

1°. When the forces are not confined to one plane, we have already found, for the square of the resultant,

$$R^2 = (\Sigma F \cos \alpha)^2 + (\Sigma F \cos \beta)^2 + (\Sigma F \cos \gamma)^2.$$

But this expression can reduce to zero only when we have

$$\Sigma F \cos \alpha = 0, \quad \Sigma F \cos \beta = 0, \quad \text{and} \quad \Sigma F \cos \gamma = 0;$$

for the three terms, being squares, are all positive quantities, and hence their sum can reduce to zero only when they are separately equal to zero.

Hence: *If a set of balanced forces applied at a single point be resolved into components along three directions at right angles to each other, the algebraic sum of the components of the forces along each of the three directions must be equal to zero, and conversely.*

2°. When the forces are all confined to one plane, let that plane be the  $x$  plane; then  $\gamma = 90^\circ$  in each case, and

$$\begin{aligned} \therefore \beta &= 90^\circ - \alpha \\ \therefore \cos \beta &= \sin \alpha \\ \therefore R^2 &= (\Sigma F \cos \alpha)^2 + (\Sigma F \sin \alpha)^2. \end{aligned}$$

Hence, for equilibrium we must have

$$(\Sigma F \cos \alpha)^2 + (\Sigma F \sin \alpha)^2 = 0;$$

and, since this is the sum of two squares,

$$\Sigma F \cos \alpha = 0, \text{ and } \Sigma F \sin \alpha = 0.$$

Hence: *If a set of balanced forces, all situated in one plane, and acting at one point, be resolved into components along two directions at right angles to each other, and in their own plane, the algebraic sum of the components along each of the two given directions must be equal to zero respectively; and conversely.*

§ 28. **Statics of Rigid Bodies.** — A rigid body is one that does not undergo any alteration of shape when subjected to the action of external forces. Strictly speaking, no body is absolutely rigid; but different bodies possess a greater or less degree of rigidity according to the material of which they are composed, and to other circumstances. When a force is applied to a rigid body, we may have as the result, not merely a rectilinear motion in the direction of the force, but, as will be shown later, this may be combined with a rotary motion; in short, the criterion by which we determine the ensuing motion is, that the effect of the force will distribute itself through the body in such a way as not to interfere with its rigidity.

What this mode of distribution is, we shall discuss hereafter; but we shall first proceed to some propositions which can be proved independently of this consideration.

§ 29. **Principle of Rectilinear Transference of Force in Rigid Bodies.** — If a force be applied to a rigid body at the point *A* (Fig. 13) in the direction *AB*, whatever be the motion that this force would produce, it will be prevented from taking place if an equal and opposite force be applied at *A*, *B*, *C*, or *D*, or at any point along the line of action of the force: hence we have the principle that —

FIG. 13.

*The point of application of a force acting on a rigid body, may be transferred to any other point which lies in the line of*

action of the force, and also in the body, without altering the resulting motion of the body, although it does alter its state of stress.

§ 30. **Composition of two Forces in a Plane acting at Different Points of a Rigid Body, and not Parallel to Each Other.** — Suppose the force  $F$  (Fig. 14) to be applied at  $A$ , and  $F_1$  at  $B$ , both in the plane of the paper, and acting on the rigid body  $abcdef$ . Produce the lines of direction of the forces till they meet at  $O$ , and suppose both  $F$  and  $F_1$  to act at  $O$ . Construct the parallelogram  $ODHE$ , where  $OD = F$  and  $OE = F_1$ ;

FIG. 14.

then will  $OH = R$  represent the resultant force in magnitude and in direction. Its point of application may be conceived at any point along the line  $OH$ , as at  $C$ , or any other point; and a force equal and opposite to

$OH$ , applied at any point of the line  $OH$ , will balance  $F$  at  $A$ , and  $F_1$  at  $B$ .

The above reasoning has assumed the points  $A$ ,  $B$ ,  $C$  and  $O$ , all within the body: but, since we have shown, that when this is the case, a force equal and opposite to  $R$  at  $C$  will balance  $F$  at  $A$ , and  $F_1$  at  $B$ , it follows, that were these three forces applied, equilibrium would still subsist if we were to remove the part  $bafegho$  of the rigid body; or, in other words, —

*The same construction holds even when the point  $O$  falls outside the rigid body.*

§ 31. **Moment of a Force with Respect to an Axis Perpendicular to the Force.**

DEFINITION. — The moment of a force with respect to an axis perpendicular to the force, and not intersecting it, is the

product of the force by the common perpendicular to (shortest distance between) the force and the axis.

Thus, in Fig. 15 the moment of  $F$  about an axis through  $O$  and perpendicular to the plane of the paper is  $F(OA)$ . The sign of the moment will depend on the sign attached to the force and that attached to the perpendicular. These will be assumed in this book in such a manner as to render the following true; viz., —

FIG. 15.

*The moment of a force with respect to an axis is called positive when, if the axis were supposed fixed, the force would cause the body on which it acts to rotate around the axis in the direction of the hands of a watch as seen by the observer looking at the face. It will be called negative when the rotation would take place in the opposite direction.*

FIG. 16.

§ 32. **Equilibrium of Three Parallel Forces applied at Different Points of a Rigid Body.** — Let it be required to find a force (Fig. 16) that will balance the two forces  $F$  at  $A$ , and  $F_1$  at  $B$ . Apply at  $A$  and  $B$  respectively, and in the line  $AB$ , the equal and opposite forces  $Aa$  and  $Bb$ . Their introduction will produce no alteration in the body's motion.

The resultant of  $F$  and  $Aa$  is  $Af$ , that of  $F_1$  and  $Bb$  is  $Bg$ . Compound these by the method of § 30, and we obtain as result-

ant  $ce$ . A force equal in magnitude and opposite in direction

to  $ce$ , applied at any point of the line  $cC$ , will be the force required to balance  $F$  at  $A$  and  $F_1$  at  $B$ ; and, as is evident from the construction, this line is in the plane of the two forces. Moreover, by drawing triangle  $fKl$  equal to  $Bbg$ , we can readily prove that triangles  $oce$  and  $Afl$  are equal: hence the angle  $oce$  equals the angle  $fAl$ , and  $R$  is parallel to  $F$  and  $F_1$ . Also

$$R = ce = ch + he = AK + Kl = F + F_1,$$

$$\frac{Cc}{AC} = \frac{AK}{fK} = \frac{F}{Aa},$$

and

$$\frac{Cc}{BC} = \frac{bg}{Bb} = \frac{F_1}{Bb};$$

$\therefore$  since  $Aa = Bb$ ,

$$\frac{AC}{BC} = \frac{F_1}{F} \therefore \frac{F}{BC} = \frac{F_1}{AC} = \frac{F + F_1}{AB} \therefore \frac{F}{Cr} = \frac{F_1}{Cq} = \frac{F + F_1}{qr},$$

where  $qr$  is any line passing through  $C$ .

Hence we have the following propositions; viz., —

*If three parallel forces balance each other, —*

1°. *They must lie in one plane.*

2°. *The middle one must be equal in magnitude and opposite in direction to the sum of the other two.*

3°. *Each force is proportional to the distance between the lines of direction of the other two as measured on any line intersecting all of them.*

The third of the above-stated conditions may be otherwise expressed, thus: —

*The algebraic sum of the moments of the three forces about any axis perpendicular to the forces must be zero.*

FIG. 17.

PROOF. — Let  $F$ ,  $F_1$ , and  $R$  (Fig. 17) be the forces; and let the axis referred to pass through  $O$ . Draw  $OA$  perpendicular to the forces. Then we have

$$\begin{aligned} F(OA) + F_1(OB) &= F(OC + CA) + F_1(OC - BC) \\ &= (F + F_1)OC + F(AC) - F_1(BC). \end{aligned}$$

But, from what we have already seen,

$$F + F_1 = -R$$

and

$$\frac{F}{BC} = \frac{F_1}{AC}$$

$$\therefore F(AC) = F_1(BC)$$

$$\therefore F(OA) + F_1(OB) = -R(OC) + 0$$

$$\therefore F(OA) + F_1(OB) + R(OC) = 0,$$

or the algebraic sum of the moments of the forces about the axis through  $O$  is equal to zero.

§ 33. **Resultant of a Pair of Parallel Forces.** — In the preceding case, the resultant of any two of the three forces  $F$ ,  $F_1$ , and  $R$ , in Fig. 16 or Fig. 17, is equal and opposite to the third force. Hence follow the two propositions:—

I. If two parallel forces act in the same direction, their resultant lies in the plane of the forces, is equal to their sum, acts in the same direction, and cuts the line joining their points of application, or any common perpendicular to the two forces, at a point which divides it internally into two segments inversely as the forces.

II. If two unequal parallel forces act in opposite directions, their resultant lies in the plane of the forces, is equal to their difference, acts in the direction of the larger force, and cuts the line joining their points of application, or any common perpendicular to them, at a point which (lying nearer the larger force)

divides it externally into two segments which are inversely as the forces.

Another mode of stating the above is as follows :—

1°. The resultant of a pair of parallel forces lies in the plane of the forces.

2°. It is equal in magnitude to their algebraic sum, and coincides in direction with the larger force.

3°. The moment of the resultant about an axis perpendicular to the plane of the forces is equal to the algebraic sum of the moments about the same axis.

#### EXAMPLES.

1. Find the length of each arm of a balance such that 1 ounce at the end of the long arm shall balance 1 pound at the end of the short arm, the length of beam being 2 feet, and the balance being so proportioned as to hang horizontally when unloaded.

2. Given beam = 28 inches, 3 ounces to balance 15.

3. Given beam = 36 inches, 5 ounces to balance 25 ounces.

#### MODE OF DETERMINING THE RESULTANT OF A PAIR OF PARALLEL FORCES REFERRED TO A SYSTEM OF THREE RECTANGULAR AXES.

Let both forces (Fig. 18) be parallel to  $OZ$ ; then we have, from what has preceded,

$$\frac{F}{bc} = \frac{F_1}{ab} = \frac{F + F_1}{ac} = \frac{R}{ac}, \text{ where } R = F + F_1.$$

But from the figure

$$\frac{bc}{x_3 - x_2} = \frac{ab}{x_2 - x_1} \quad \therefore \quad \frac{F}{x_3 - x_2} = \frac{F_1}{x_2 - x_1}$$

$$\therefore Fx_2 - Fx_1 = F_1x_3 - F_1x_2$$

$$\therefore (F + F_1)x_2 = Fx_1 + F_1x_3,$$

or

$$Rx_2 = Fx_1 + F_1x_3;$$

and similarly we may prove that

$$Ry_2 = Fy_1 + F_1y_3,$$

or

1°. The resultant of two parallel forces is parallel to the forces and equal to their algebraic sum.

FIG. 18.

2°. The moment of the resultant with respect to  $OX$  is equal to the algebraic sum of their moments with respect to  $OX$ ; and likewise when the moments are taken with respect to  $OY$ .

§ 34. Resultant of any Number of Parallel Forces.— Let it be required to find the resultant of any number of parallel forces.

In any such case, we might begin by compounding two of them, and then compounding the resultant of these two with a third, this new resultant with a fourth, and so on. Hence, for the magnitude of any one of these resultants, we simply add to the preceding resultant another one of the forces; and for the moment about any axis perpendicular to the forces, we add

to the moment of the preceding resultant the moment of the new force.

Hence we have the following facts in regard to the resultant of the entire system : —

1°. *The resultant will be parallel to the forces and equal to their algebraic sum.*

2°. *The moment of the resultant about any axis perpendicular to the forces will be equal to the algebraic sum of the moments of the forces about the same axis.*

The above principles enable us to determine the resultant in all cases, except when the algebraic sum of the forces is equal to zero. This case will be considered later.

### § 35. Composition of any System of Parallel Forces when all are in One Plane. —

Refer the forces to a pair of rectangular axes,  $OX$ ,  $OY$  (Fig. 19), and assume  $OY$  parallel to the forces.

FIG. 19.

The forces and the co-ordinates of their lines of direction being as indicated in the figure, if we denote by  $R$  the resultant, and by  $x_0$  the co-ordinate of its line of direction, we shall have, from the preceding,

$$R = \Sigma F; \quad (1)$$

and if moments be taken about an axis through  $O$ , and perpendicular

to the plane of the forces, we shall also have

$$Rx_0 = \Sigma Fx. \quad (2)$$

Hence

$$R = \Sigma F \quad \text{and} \quad x_0 = \frac{\Sigma Fx}{\Sigma F}$$

determine the resultant in magnitude and in line of action, except when  $\Sigma F = 0$ , which case will be considered later.

§ 36. **Composition of any System of Parallel Forces not confined to One Plane.** — Refer the forces to a set of rectangular axes so chosen that  $OZ$  is parallel to their direction. If we denote the forces by  $F_1, F_2, F_3, F_4$ , etc., and the co-ordinates of their lines of direction by  $(x_1, y_1), (x_2, y_2)$ , etc., and if we denote their resultant by  $R$ , and the co-ordinates of its line of direction by  $(x_0, y_0)$ , we shall have, in accordance with what has been proved in § 34, —

1°. *The magnitude of the resultant about  $OY$  is equal to the algebraic sum of the forces, or*

$$R = \Sigma F.$$

2°. *The moment of the resultant about  $OY$  is equal to the sum of the moments of the forces about  $OY$ , or*

$$x_0 \Sigma F = \Sigma Fx.$$

3°. *The moment of the resultant about  $OX$  is equal to the sum of the moments about  $OX$ , or*

$$y_0 \Sigma F = \Sigma Fy.$$

Hence

$$R = \Sigma F, \quad x_0 = \frac{\Sigma Fx}{\Sigma F}, \quad y_0 = \frac{\Sigma Fy}{\Sigma F},$$

determine the resultant in all cases, except when  $\Sigma F = 0$ .

§ 37. **Conditions of Equilibrium of any Set of Parallel Forces.** — If the axes be assumed as before, so that  $OZ$  is parallel to the forces, we must have

$$\Sigma F = 0, \quad \Sigma Fx = 0, \quad \text{and} \quad \Sigma Fy = 0.$$

To prove this, compound all but one of the forces. Then equilibrium will subsist only when the resultant thus obtained is equal and directly opposed to the remaining force; i.e., it must be equal, and act along the same line and in the opposite direction. Hence, calling  $R_a$  the resultant above referred to, and  $(x_a, y_a)$  the co-ordinates of its line of direction, and calling  $F_n$  the

remaining force, and  $(x_n, y_n)$  the co-ordinates of its line of direction, we must have

$$\begin{aligned} R_a &= -F_n, & x_a &= x_n, & y_a &= y_n, \\ \therefore R_a + F_n &= 0, & R_ax_a + F_nx_n &= 0, & R_ay_a + F_ny_n &= 0, \\ \therefore \Sigma F &= 0, & \Sigma Fx &= 0, & \Sigma Fy &= 0. \end{aligned}$$

When the forces are all in one plane, the conditions become

$$\Sigma F = 0, \quad \Sigma Fx = 0.$$

§ 38. **Centre of a System of Parallel Forces.** — The resultant of the two parallel forces  $F$  and  $F_1$  (Fig. 20), applied at  $A$  and  $B$  respectively, is a force  $R = F + F_1$ , whose line of action cuts the line  $AB$  at a point  $C$ , which divides it into two segments inversely as the forces. If the forces  $F$  and  $F_1$  are turned through the same angle, and assume the positions  $AO$  and  $BO_1$  respectively, the line of action of the resultant will still pass through  $C$ , which is called the centre of the two parallel forces  $F$  and  $F_1$ . Inasmuch as a similar reasoning will apply in the case of any number of parallel forces, we may give the following definition:—

FIG. 20.

*The centre of a system of parallel forces is the point through which the line of action of the resultant always passes, no matter how the forces are turned, provided only —*

- 1°. *Their points of application remain the same.*
- 2°. *Their relative magnitudes are unchanged.*
- 3°. *They remain parallel to each other.*

Hence, in finding the centre of a set of parallel forces, we may suppose the forces turned through any angle whatever, and the centre of the set is the point through which the line of action of the resultant always passes.

§ 39. **Co-ordinates of the Centre of a Set of Parallel Forces.** — Let  $F_1$  (Fig. 21) be one of the forces, and  $(x_1, y_1, z_1)$  the co-ordinates of its point of application. Let  $F_2$  be another, and  $(x_2, y_2, z_2)$  co-ordinates of its point of application. Turn all the forces around till they are parallel to  $OZ$ , and find the line of direction of the resultant force when they are in this position. The co-ordinates of this line are

FIG. 21.

$$x_o = \frac{\sum Fx}{\sum F}, \quad y_o = \frac{\sum Fy}{\sum F};$$

and, since the centre of the system is a point on this line, the above are two of the co-ordinates of the centre. Then turn the forces parallel to  $OX$ , and determine the line of action of the resultant. We shall have for its co-ordinates

$$y_o = \frac{\sum Fy}{\sum F}, \quad z_o = \frac{\sum Fz}{\sum F}.$$

Hence, for the co-ordinates of the centre of the system, we have

$$x_o = \frac{\sum Fx}{\sum F}, \quad y_o = \frac{\sum Fy}{\sum F}, \quad z_o = \frac{\sum Fz}{\sum F}.$$

When  $\sum F = 0$  the co-ordinates would be  $\infty$ , therefore such a system has no centre.

§ 40. **Distributed Forces.** — While we have thus far assumed our forces as acting at single points, no force really acts at a single point, but all are distributed over a certain surface

or through a certain volume; nevertheless, the propositions already proved are all applicable to the resultants of these distributed forces. We shall proceed to discuss distributed forces only when all the elements of the distributed force are parallel to each other. As a very important example of such a distributed force, we may mention the force of gravity which is distributed through the mass of the body on which it acts. Thus, the weight of a body is the resultant of the weights of the separate parts or particles of which it is composed. As another example we have the following: if a straight rod be subjected to a direct pull in the direction of its length, and if it be conceived to be divided into two parts by a plane cross-section, the stress acting at this section is distributed over the surface of the section.

**§ 41. Intensity of a Distributed Force.** — Whenever we have a force uniformly distributed over a certain area, we obtain its *intensity* by dividing its total amount by the area over which it acts, thus obtaining the amount per unit of area.

If the force be not uniformly distributed, or if the intensity vary at different points, we must adopt the following means for finding its intensity. Assume a small area containing the point under consideration, and divide the total amount of force that acts on this small area by the area, thus obtaining the *mean intensity* over this small area: this will be an approximation to the intensity at the given point; and the intensity is the limit of the ratio obtained by making the division, as the area used becomes smaller and smaller.

Thus, also, the *intensity*, at a given point, of a force which is distributed through a certain volume, is the limit of the ratio of the force acting on a small volume containing the given point, to the volume, as the latter becomes smaller and smaller.

**§ 42. Resultant of a Distributed Force.** — 1°. Let the force be distributed over the straight line  $AB$  (Fig. 22), and

let its intensity at the point  $E$  where  $AE = x$ , be represented by  $EF = p = \phi(x)$ , a function of  $x$ ; then will the force acting on the portion  $Ee = \Delta x$  of the line be  $p\Delta x$ : and if we denote by  $R$  the magnitude of the resultant of the force acting on the entire line  $AB$ , and by  $x_0$  the distance of its point of application from  $A$ , we shall have

FIG. 22.

$$R = \Sigma p\Delta x \text{ approximately,}$$

or

$$R = \int p dx \text{ exactly;}$$

and, by taking moments about an axis through  $A$  perpendicular to the plane of the force, we shall have

$$x_0 R = \Sigma x(p\Delta x) \text{ approximately,}$$

or

$$x_0 R = \int p x dx \text{ exactly;}$$

whence we have the equations

$$R = \int p dx, \quad x_0 = \frac{\int p x dx}{\int p dx}.$$

2°. Let the force be distributed over a plane area  $EFGH$

FIG. 23.

(Fig. 23), let this area be referred to a pair of rectangular axes  $OX$  and  $OY$ , in its own plane, and let the intensity of the force per unit of area at the point  $P$ , whose coordinates are  $x$  and  $y$ , be  $p = \phi(x, y)$ ; then will  $p\Delta x\Delta y$  be approximately the force acting on the small rectangular area  $\Delta x\Delta y$ . Then, if we represent by  $R$  the magnitude of

the resultant of the distributed force, and by  $x_0, y_0$  the co-ordi-

nates of the point at which the line of action of the resultant cuts the plane of  $EFGH$ , we shall have

$$\begin{aligned} R &= \Sigma p \Delta x \Delta y \text{ approximately,} \\ x_o R &= \Sigma x (p \Delta x \Delta y) \quad " \\ y_o R &= \Sigma y (p \Delta x \Delta y) \quad " \end{aligned}$$

• or, as exact equations, we shall have

$$\begin{aligned} R &= \iint p dx dy, \\ x_o &= \frac{\iint p x dx dy}{\iint p dx dy}, \quad y_o = \frac{\iint p y dx dy}{\iint p dx dy}. \end{aligned}$$

§°. Let the force be distributed through a volume, let this volume be referred to a system of rectangular axes,  $OX$ ,  $OY$ , and  $OZ$ , let  $\Delta V$  represent the elementary volume, whose co-ordinates are  $x$ ,  $y$ ,  $z$ , and let  $p = \phi(x, y, z)$  be the intensity of the force per unit of volume at the point  $(x, y, z)$ ; then, if we represent by  $R$  the magnitude of the resultant, and by  $x_o$ ,  $y_o$ ,  $z_o$  the co-ordinates of the centre of the distributed force, we shall have, from the principles explained in § 38 and § 39, the approximate equations

$$R = \Sigma p \Delta V, \quad x_o R = \Sigma x (p \Delta V), \quad y_o R = \Sigma y (p \Delta V), \quad z_o R = \Sigma z (p \Delta V);$$

and these give, on passing to the limit, the exact equations

$$R = \int p dV, \quad x_o = \frac{\int p x dV}{\int p dV}, \quad y_o = \frac{\int p y dV}{\int p dV}, \quad z_o = \frac{\int p z dV}{\int p dV}.$$

§ 43. **Centre of Gravity.** — The weight of a body, or system of bodies, is the resultant of the weight of the separate parts or particles into which it may be conceived to be divided; and the *centre of gravity* of the body, or system of bodies, is the centre of the above-stated system of parallel forces, i.e., the point through which the resultant always passes, no matter how the forces are turned. The weight of any one particle is the force which gravity exerts on that particle: hence, if we repre-

sent the weight per unit of volume of a body, whether it be the same for all parts or not, by  $w$ , we shall have, as an approximation,

$$W = \Sigma w \Delta V, \quad x_o = \frac{\Sigma wx \Delta V}{\Sigma w \Delta V}, \quad y_o = \frac{\Sigma wy \Delta V}{\Sigma w \Delta V}, \quad z_o = \frac{\Sigma wz \Delta V}{\Sigma w \Delta V};$$

and as exact equations,

$$W = \int w dV, \quad x_o = \frac{\int wx dV}{\int w dV}, \quad y_o = \frac{\int wy dV}{\int w dV}, \quad z_o = \frac{\int wz dV}{\int w dV}, \quad (1)$$

where  $W$  denotes the entire weight of the body, and  $x_o, y_o, z_o$ , the co-ordinates of its centre of gravity.

If, on the other hand, we let  $M$  = entire mass of the body,  $dM$  = mass of volume  $dV$ , and  $m$  = mass of unit of volume, we shall have

$$W = Mg, \quad w = mg, \quad w dV = mg dV = g dM.$$

Hence the above equations reduce to

$$M = \int dM, \quad x_o = \frac{\int x dM}{\int dM}, \quad y_o = \frac{\int y dM}{\int dM}, \quad z_o = \frac{\int z dM}{\int dM}. \quad (2)$$

Equations (1) and (2) are both suitable for determining the centre of gravity; one of the sets being sometimes most convenient, and sometimes the other.

**§ 44. Centre of Gravity of Homogeneous Bodies.**—If the body whose centre of gravity we are seeking is homogeneous, or of the same weight per unit of volume throughout, we shall have, that  $w$  = a constant in equations (1); and hence these reduce to

$$W = w \int dV, \quad x_o = \frac{\int x dV}{\int dV}, \quad y_o = \frac{\int y dV}{\int dV}, \quad z_o = \frac{\int z dV}{\int dV}.$$

**§ 45. Effect of a Single Force applied at the Centre of a Straight Rod of Uniform Section and Material.**—If a straight rod of uniform section and material have imparted to it

a motion, such that the velocity imparted in a unit of time to each particle of the rod is the same, and if we represent this velocity by  $f$ , then if at each point of the rod, we lay off a line

FIG. 24.

$xy$  (Fig. 24) in the direction of the motion, and representing the velocity imparted to that point, the line bounding the other ends of the lines  $xy$  will be straight, and parallel to the rod. If we conceive the rod to be divided into any number of small equal parts, and denote the mass of one of these parts by  $\Delta M$ , then will  $f\Delta M$  contain as many units of momentum as there are units of force in the force required to impart to this particle the velocity  $f$  in a unit of time; and hence  $f\Delta M$  is the measure of this force.

Hence the resultant of the forces which impart the velocity  $f$  to every particle of the rod will have for its measure

$$fM,$$

where  $M$  is the entire mass of the rod; and its point of application will evidently be at the middle of the rod.

It therefore follows that —

*The effect of a single force applied at the middle of a straight rod of uniform section and material is to impart to the rod a motion of translation in the direction of the force, all points of the rod acquiring equal velocities in equal times.*

§46. Translation and Rotation combined. — Suppose that we have a straight rod  $AB$  (Fig. 25), and suppose that such a force or such forces are applied to it as will impart to the point  $A$  in a unit of time the velocity  $Aa$ , and to the point  $B$  the (different) velocity  $Bb$  in a unit of time, both being perpendicular to the length of the rod. It is required to determine the motion of any other point of the rod and that of the entire rod.

Lay off  $Aa$  and  $Bb$  (Fig. 25), and draw the line  $ab$ , and produce it till it meets  $AB$  produced in  $O$ : then, when these velocities  $Aa$  and  $Bb$  are imparted to the points  $A$  and  $B$ , the rod is in the act of rotating around an axis through  $O$  perpendicular to the plane of the paper; for when a body is rotating around an axis, the linear velocity of any point of the body is perpendicular to the line joining the point in question with the axis (i.e., the perpendicular dropped from the point in question upon the axis), and proportional to the distance of the point from the axis.

FIG. 25.

Hence: *If the velocities of two of the points in the rod are given, and if these are perpendicular to the rod, the motion of the rod is fixed, and consists of a rotation about some axis at right angles to the rod.*

Another way of considering this motion is as follows: Suppose, as before, the velocities of the points  $A$  and  $B$  to be represented by  $Aa$  and  $Bb$  respectively, and hence the velocity of any other point, as  $x$  (Fig. 26), to be represented by  $xy$ , or the length of the line drawn perpendicular to  $AB$ , and limited by  $AB$  and  $ab$ .

FIG. 26.

Then, if we lay off  $Aa_1 = Bb_1 = \frac{1}{2}(Aa + Bb) = Cc$ , and draw  $a_1b_1$ , and if we also lay off  $Aa_2 = a_2a$ , and  $Bb_2 = b_2b$ , we shall have the following relations; viz., —

$$\begin{aligned} Aa &= Aa_1 - Aa_2, \\ Bb &= Bb_1 + Bb_2, \\ xy &= xy_1 - xy_2, \text{ etc.,} \end{aligned}$$

or we may say that the actual motion imparted to the rod in a unit of time may be considered to consist of the following two parts: —

1°. A velocity of translation represented by  $Aa_1$ , the mean velocity of the rod; all points moving with this velocity.

2°. A varying velocity, different for every different point, and such that its amount is proportional to its distance from  $C$ , the centre of the rod, as graphically shown in the triangles  $Aa_1Cb_1$ . In other words, the rod has imparted to it two motions:—

1°. A translation with the mean velocity of the rod.

2°. A rotation of the rod about its centre.

§ 47. **Effect of a Force applied to a Straight Rod of Uniform Section and Material, not at its Centre.**—If the force be not at right angles to the rod, resolve it into two components, one acting along the rod, and the other at right angles to it. The first component evidently produces merely a translation of the rod in the direction of its length: hence the second component is the only one whose effect we need to study.

To do this we shall proceed to show, that, when such a rod

FIG. 27.

has imparted to it the motion described in § 46, the single resultant force which is required to impart this motion in a unit of time is a force acting at right angles to the rod, at a point different from its centre; and we shall determine the relation between the force and the motion imparted, so that one may be deduced from the other.

Let  $A$  be the origin (Fig. 27), and let

$Ac = x$ ,  $cd = dx$ .

$AB = l$  = length of the rod.

$ce = f$  = velocity imparted per unit of time at distance  $x$  from  $A$ .

$Aa = f_1$ ,  $Bb = f_2$ .

$w$  = weight per unit of length.

$m$  = mass per unit of length =  $\frac{w}{g}$ .

$W$  = entire weight of rod.

$M$  = entire mass of rod  $= \frac{W}{g}$ .

$R$  = single resultant force acting for a unit of time to produce the motion.

$x_0$  = distance from  $A$  to point of application of  $R$ .

Then we shall have,

$$f = f_1 + \frac{f_2 - f_1}{l} x.$$

Hence, from § 42,

$$R = m \int_0^l f dx = m(\text{area } AabB) = \frac{m}{2}(f_1 + f_2)l = \frac{M}{2}(f_1 + f_2). \quad (1)$$

$$x_0 R = m \int_0^l f x dx = \frac{m}{6}(f_1 + 2f_2)l^2 = \frac{M}{6}(f_1 + 2f_2)l. \quad (2)$$

$$\therefore x_0 = \frac{1}{3} \frac{f_1 + 2f_2}{f_1 + f_2} l. \quad (3)$$

We thus have a force  $R$ , perpendicular to  $AB$ , whose magnitude is given by equation (1), and whose point of application is given by equation (3); the respective velocities imparted by the force being shown graphically in Fig. 27.

#### EXAMPLES.

1. Given Weight of rod  $= W = 100$  lbs.,  
 Length of rod  $= 3$  feet,  
 Assume  $g = 32$  feet per second,  
 Force applied  $= R = 5$  lbs.,  
 Point of application to be 2.5 feet from one end;

determine the motion imparted to the rod by the action of the force for one second.

*Solution.*

Equation (1) gives us,

$$5 = \left(\frac{100}{32}\right) \frac{f_1 + f_2}{2}, \text{ or } f_1 + f_2 = 3.2.$$

Equation (2) gives,

$$(2.5)(5) = \left(\frac{100}{32}\right) \left(\frac{1}{6}\right) (3)(f_1 + 2f_2), \text{ or } f_1 + 2f_2 = 8$$

$$\therefore f_2 = 4.8, \quad f_1 = -1.6.$$

Hence the rod at the end nearest the force acquires a velocity of 4.8 feet per second, and at the other end a velocity of  $-1.6$  feet per second. The mean velocity is, therefore, 1.6 feet per second; and we may consider the rod as having a motion of translation in the direction of the force with a velocity of 1.6 feet per second, and a rotation about its centre with such a speed that the extreme end (i.e., a point  $\frac{3}{2}$  feet from the centre) moves at a velocity  $4.8 - 1.6 = 3.2$  feet per second. Hence angular velocity  $= \frac{3.2}{1.5} = 2.14$  per second  $= 122^\circ.6$  per second.

2. Given  $W = 50$  lbs.,  $l = 5$  feet. It is desired to impart to it, in one second, a velocity of translation at right angles to its length, of 5 feet per second, together with a rotation of 4 turns per second: find the force required, and its point of application.

3. Assume in example 2 that the velocity of translation is in a direction inclined  $45^\circ$  to the length of the rod, instead of  $90^\circ$ . Solve the problem.

4. Given a force of 3 lbs. acting for one-half a second at a distance of 4 feet from one end of the rod, and inclined at  $30^\circ$  to the rod: determine its motion.

5. Given the same conditions as in example 4, and also a force of 4 lbs., parallel and opposite in direction to the 3-lb. force, and acting also for one-half a second, and applied at 3 feet from the other end: determine the resulting motion.

6. Given two equal and opposite parallel forces, each acting at right angles to the length of the rod, and each equal to 4 lbs., one being applied at 1 foot from one end, and the other at the middle of the rod; find the motion imparted to the rod through the joint action of these forces for one-third of a second.

§ 48. **Moment of the Forces causing Rotation.** — Referring again to Fig. 26, and considering the motion of the rod as a combination of translation and rotation, if we take moments about the centre  $C$ , and compare the total moment of the forces causing the rotation alone, whose accelerations are represented by the triangles  $aa,cb,b$ , with the total moment of the actual forces acting, whose accelerations are represented by the trapezoid  $AabB$ , we shall find these moments equal to each other; for, as far as the forces represented by the rectangle are concerned, every elementary force  $m(xy, )dx$  on one side of the centre  $C$  has its moment  $(Cx)\{m(xy, )dx\}$  equal and opposite to that of the elementary force at the same distance on the other side of  $C$ : hence the total moment of the forces represented graphically by the rectangle  $Aa,b,B$  is zero, and hence —

*The moment about  $C$  of those represented by the trapezoid equals the moment of those represented by the triangles.*

Hence, from the preceding, and from what has been previously proved, we may draw the following conclusions: —

1°. If a force be applied at the centre of the rod, it will impart the same velocity to each particle.

2°. If a force be applied at a point different from the centre, and act at right angles to its length, it will cause a translation of the rod, together with a rotation about the centre of the rod.

3°. In this latter case, the moment of the forces imparting the rotation alone is equal to the moment of the single resultant force about the centre of the rod, and the velocity of translation imparted in a unit of time is equal to the number of units of force in the force, divided by the entire mass of the rod.

§ 49. **Effect of a Pair of Equal and Opposite Parallel Forces applied to a Straight Rod of Uniform Section and Material.** — Suppose the rod to be  $AB$  (Fig. 28), and let the two equal and opposite parallel forces be  $Dd$  and  $Ee$ , each equal to  $F$ , applied at  $D$  and  $E$  respectively.

FIG. 28.

The mean velocity imparted in a unit of time by either force will be  $\frac{F}{M}$ ; and, from what we have already seen, the trapezoid  $AabB$  will furnish us the means of representing the actual velocity imparted to any point of the rod by the force  $Dd$ . The relative magnitudes of  $Aa$  and  $Bb$ , the accelerations at the ends, will depend, of course, on the position of  $D$ ; but we shall always have  $Cc = \frac{1}{2}(Aa + Bb) = \frac{F}{M}$ , a quantity depending only on the *magnitude* of the force. So, likewise, the trapezoid  $Aa_1b_1B$  will represent the velocities imparted by the force  $Ee$ ; and while the relative magnitude of  $Aa_1$  and  $Bb_1$  will depend upon the position of  $E$ , we shall always have  $Cc_1 = \frac{1}{2}(Aa_1 + Bb_1) = \frac{F}{M}$ . Hence, since  $Cc = Cc_1$ , the centre  $C$  of the rod has no motion imparted to it by the given pair of forces, hence the motion of the rod is one of rotation about its centre  $C$ .

The resulting velocity of any point of the rod will be the difference between the velocities imparted by the two forces; and if these be laid off to scale, we shall have the second figure. Hence —

*A pair of equal and opposite parallel forces, applied to a straight rod of uniform section and material, produce a rotation of the rod about its centre. Also, —*

*Such a rotation about the centre of the rod cannot be pro-*

duced by a single force, but requires a pair of equal and opposite parallel forces.

§ 50. **Statical Couple.** — A pair of equal and opposite parallel forces is called a statical couple.

§ 51. **Effect of a Single Force applied at the Centre of Gravity of a Straight Rod of Non-Uniform Section and Material.** — In the case of a straight rod of non-uniform section and material, we may consider the rod as composed of a set of particles of unequal mass: and if we imagine each particle to have imparted to it the same velocity in a unit of time, then, using the same method of graphical representation as before (Fig. 24), the line  $ab$ , bounding the other ends of the lines representing velocities, will be parallel to  $AB$ ; but if we were to represent by the lines  $xy$ , not the velocities imparted, but the forces per unit of length, the line bounding the other ends of these forces would not, in this case, be parallel to  $AB$ . Moreover, since these forces are proportional to the masses, and hence to the weights of the several particles, their resultant would act at the centre of gravity of the rod. Hence —

*A force applied at the centre of gravity of a straight rod will impart the same velocity to each point of the rod; i.e., will impart to it a motion of translation only.*

§ 52. **Effect of a Statical Couple on a Straight Rod of Non-Uniform Section and Material.** — Let such a rod have imparted to it only a motion of rotation about its centre of gravity, and let us adopt the same modes of graphical representation as before.

Let the origin be taken at  $O$  (Fig. 29), the centre of gravity of the rod.

Let  $Aa = f_1 =$  velocity imparted to  $A$ .

$Bb = f_2 =$  velocity imparted to  $B$ .

$OA = a, OB = b, OC = x$ .

$CD = f =$  velocity imparted to  $C$ .

$dM =$  elementary mass at  $C$ .

FIG. 29.

Then, from similar triangles, we have

$$f = \frac{f_1}{a}x = \frac{f_2}{b}x,$$

and hence for the force acting on  $dM$  we have

$$dF = (CE)dx = \frac{f_1}{a}xdM.$$

Hence the whole force acting on  $AO$ , and represented graphically by  $Aa,O$ , is

$$\frac{f_1}{a} \int_{x=-b}^{x=a} xdM,$$

and that acting on  $OB$ , and represented by  $BOb$ , is

$$\frac{f_2}{b} \int_{x=-b}^{x=0} xdM = \frac{f_1}{a} \int_{x=-b}^{x=0} xdM.$$

Hence for the resultant, or the algebraic sum, of the two, we have

$$R = \frac{f_1}{a} \int_{x=-b}^{x=a} xdM.$$

But from § 43 we have for the co-ordinate  $x_0$  of the centre of gravity of the rod

$$x_0 = \frac{\int_{x=-b}^{x=a} xdM}{M};$$

but, since the origin is at the centre of gravity, we have

$$x_0 = 0,$$

and hence

$$\int_{x=-b}^{x=a} xdM = 0 \quad \therefore R = 0.$$

Hence the two forces represented by  $Aa,O$  and  $Bb,O$  are equal in magnitude and opposite in direction: hence the rotation about the centre of gravity is produced by a *Statical Couple*.

Now, a train of reasoning similar to that adopted in the case of a rod of uniform section and material will show that a single force applied at some point which is not the centre of gravity of the rod will produce a motion which consists of two parts; viz., a motion of translation, where all points of the rod have equal velocities, and a motion of rotation around the centre of gravity of the rod.

§ 53. **Moment of a Couple.**—The *moment of a statical couple* is the product of either force by the perpendicular distance between the two forces, this perpendicular distance being called the arm of the couple.

§ 54. **Measure of the Rotatory Effect.**—Before proceeding to examine the effect of a statical couple upon any rigid body whatever, we will seek a means of measuring its effect in the cases already considered.

The measure adopted is the moment of the couple; and, in order to show that it is proper to adopt this measure, it will be necessary to show—

That the moment of the couple is proportional to the angular velocity imparted to the same rod in a unit of time; and from this it will follow—

That two couples in the same plane with equal moments will balance each other if one is right-handed and the other left-handed.

If we assume the origin of co-ordinates at  $C$  (Fig. 30), the centre of gravity of the rod, and if we denote by  $\alpha$  the angular velocity imparted in a unit of time by the forces  $F$  and  $-F$ , and let  $CD = x_1$ ,  $CE = x_2$ , then we have for the linear velocity of a particle situated at a distance  $x$  from  $C$  the value

$$\alpha x.$$

FIG. 30.

The force which will impart this velocity in a unit of time to the mass  $dM$  is

$$\alpha x dM.$$

The total resultant force is

$$\alpha \int x dM,$$

which, as we have seen, is equal to zero. The moment of the elementary force about  $C$  is

$$x(\alpha x dM) = \alpha x^2 dM,$$

and the sum of the moments for the whole rod is

$$\alpha \int x^2 dM,$$

and this, as is evident if we take moments about  $C$ , is equal to

$$Fx_1 - Fx_2 = F(x_1 - x_2) = F(DE).$$

Now,  $\int x^2 dM$  is a constant for the same rod: hence any quantity proportional to  $F(DE)$  is also proportional to  $\alpha$ .

The above proves the proposition.

Moreover, we have

$$\begin{aligned} F(DE) &= \alpha \int x^2 dM \\ \therefore \alpha &= \frac{F(DE)}{\int x^2 dM}, \end{aligned}$$

whence it follows, that when the moment of the couple is given, and also the rod, we can find the angular velocity imparted in a unit of time by dividing the former by  $\int x^2 dM$ .

**§ 55. Effect of a Couple on a Straight Rod when the Forces are inclined to the Rod.**—We shall next show that the effect of such a couple is the same as that of a couple of equal moment whose forces are perpendicular to the rod.

FIG. 31.

In this case let  $AD$  and  $BC$  be the forces (Fig. 31). The moment of this couple is the product of  $AD$  by the perpendicular distance between  $AD$  and  $BC$ , the graphical representation of this being

the area of the parallelogram  $ADBC$ .

Resolve the two forces into components along and at right angles to the rod. The former have no effect upon the motion of the rod: the latter are the only ones that have any effect upon its motion. The moment of the couple which they form is the product of  $Ad$  by  $AB$ , graphically represented by parallelogram  $AdBb$ ; and we can readily show that

$$ADBC = AdBb.$$

Hence follows the proposition.

§ 56. Effect of a Statical Couple on any Rigid Body. — Refer the body (Fig. 32) to three rectangular axes,  $OX$ ,  $OY$ , and  $OZ$ , assuming the origin at the centre of gravity of the body, and  $OZ$  as the axis about which the body is rotating. Let the mass of the particle  $P$  be  $\Delta M$ , and its co-ordinates be  $x, y, z$ .

FIG. 32.

Then will the force that would impart to the mass  $\Delta M$  the angular velocity  $\alpha$  in a unit of time be

$$\alpha r \Delta M,$$

where  $r$  = perpendicular from  $P$  on  $OZ$ , or

$$r = \sqrt{x^2 + y^2}.$$

This force may be resolved into two, one parallel to  $OY$  and the other to  $OX$ ; the first component being  $\alpha x \Delta M$ , and the second  $\alpha y \Delta M$ .

Proceeding in the same way with each particle, and finding the resultant of each of these two sets of parallel forces, we shall obtain, finally, a single force parallel to  $OY$  and equal to

$$\alpha \Sigma x \Delta M,$$

and another parallel to  $OX$ , equal to

$$\alpha \Sigma y \Delta M.$$

But, since  $OZ$  passes through the centre of gravity of the body, we shall have.

$$\sum x \Delta M = 0 \quad \text{and} \quad \sum y \Delta M = 0.$$

Hence the resultant is in each case, not a single force, but a *statical couple*; the moment of the first couple being

$$a \sum x^2 \Delta M,$$

and that of the second

$$a \sum y^2 \Delta M.$$

These couples produce the same effect in whatever plane perpendicular to  $OZ$  they are situated. Hence, suppose them both in the plane  $XOY$ , then representing them as in (Fig. 33), we make

$$F_1(AB) = a \sum x^2 \Delta M \quad \text{and} \quad F_2(CD) = a \sum y^2 \Delta M.$$

Now, compound the force at  $D$  with that at  $B$ , and the force at  $C$  with that at  $A$ , and we obtain as a result two equal and opposite parallel forces, or *one* statical couple, whose moment will be shown to be equal to

FIG. 33.

$$a(\sum x^2 \Delta M + \sum y^2 \Delta M) = a \sum (x^2 + y^2) \Delta M = a \sum r^2 \Delta M.$$

To show this, let

$$OB = p_1 = \text{one-half the arm of } a \sum x^2 \Delta M,$$

$$OD = p_2 = \text{one-half the arm of } a \sum y^2 \Delta M,$$

$$Oe = p = \text{one-half the arm of the resultant couple.}$$

Let angle  $DOe = \theta = GEK$ : we shall then have

$$p = Oe = Of + fe = p_2 \cos \theta + p_1 \sin \theta;$$

but

$$\cos \theta = \frac{F_2}{R}, \quad \sin \theta = \frac{F_1}{R},$$

$$\therefore p = \frac{p_2 F_2}{R} + \frac{p_1 F_1}{R}$$

$$\therefore Rp = F_1 p_1 + F_2 p_2.$$

Hence the moment of the resultant couple is equal to the sum of the moments of the separate couples, or

$$R(2p) = a \sum r^2 \Delta M = a \sum x^2 \Delta M + a \sum y^2 \Delta M.$$

Hence: *To impart to a body a rotation about an axis passing through its centre of gravity requires the action of a statical couple, and conversely a statical couple so applied will cause such a rotation as that described.*

Hence we may generalize all our propositions in regard to the effect of statical couples and we may conclude that—

*In order that two couples may have the same effect, it is necessary—*

- 1°. *That they be in the same or parallel planes.*
- 2°. *That they have the same moment.*
- 3°. *That they tend to cause rotation in the same direction (i.e., both right-handed or both left-handed when looked at from the same side).*

*It also follows, that, for a given statical couple, we may substitute another having the magnitudes of its forces different, provided only the moment of the couple remains the same.*

§ 57. **Composition of Couples in the Same or Parallel Planes.**—If the forces of the couples are not the same, reduce them to equivalent couples having the same force, transfer them to the same plane, and turn them so that their arms shall lie in the same straight line, as in Fig. 34; the first couple consisting of the force  $F$  at  $A$  and  $-F$  at  $B$ , and the second of  $F$  at  $B$  and  $-F$  at  $C$ .

FIG. 34.

The two equal and opposite forces counterbalance each other, and we have left a couple with force  $F$  and arm

$$AC = AB + BC$$

$$\therefore \text{Resultant moment} = F \cdot AC = F(AB) + F(BC).$$

**Hence:** *The moment of the couple which is the resultant of two or more couples in the same or parallel planes is equal to the algebraic sum of the moments of the component couples.*

#### EXAMPLES.

1. Convert a couple whose force is 5 and arm 6 to an equivalent couple whose arm is 3. Find the resultant of this and another couple in the same plane and sense whose force is 7 and arm 8; also find the force of the resultant couple when the arm is taken as 5.

#### Solution.

$$\begin{aligned} \text{Moment of first couple} &= 5 \times 6 = 30 \\ \text{When arm is 3, force} &= \frac{30}{3} = 10 \\ \text{Moment of second couple} &= 7 \times 8 = 56 \\ \text{Moment of resultant couple} &= 30 + 56 = 86 \\ \text{When arm is 5, force} &= \frac{86}{5} = 17\frac{1}{5} \end{aligned}$$

2. Given the following couples in one plane: —

| Force. | Arm. |   | Force. | Arm. |
|--------|------|---|--------|------|
| 12     | 17   | } Convert to equivalent couples having the following: — | 5      |      |
| 3      | 8    |   |        | 6    |
| 5      | 7    |   | 8      |      |
| 6      | 9    |   | 6      |      |
| 12     | 12   |   |        | 7    |
| 10     | 9    |   | 4      |      |
| 14     | 6    |   |        | 20   |

The first and the last three are right-handed; the second, third, and fourth are left-handed. Find the moment of the resultant couple, and also its force when it has an arm 11.

§ 58. **Representation of a Couple by a Line.**—From the preceding we see that the effect of a couple remains the same as long as —

- 1°. *Its moment does not change.*
- 2°. *The direction of its axis (i.e., of the line drawn perpendicular to the plane of the couple) does not change.*
- 3°. *The direction in which it tends to make the body turn (right-handed or left-handed) remains the same.*

Hence a couple may be represented by drawing a line in the direction of its axis (perpendicular to its plane), and laying off on this line a distance containing as many units of length as there are units of moment in the couple, and indicating by a dot, an arrow-head, or some other means, in what direction one must look along the line in order that the rotation may appear right-handed.

This line is called the *Moment Axis* of the couple.

§ 59. **Composition of Couples situated in Planes inclined to Each Other.**—Suppose we have two couples situated neither in the same plane nor in parallel planes, and that we wish to find their resultant couple. We may proceed as follows: Substitute for them equivalent couples with equal arms, then transfer them in their own plane respectively to such positions that their arms shall coincide, and lie in the line of intersection of the two planes.

This having been done, let  $OO_1$  (Fig. 35) be the common arm,  $F$  and  $-F$  the forces of one couple,  $F_1$  and  $-F_1$  those of the other. The forces  $F$  and  $F_1$  have for their resultant  $R$ , and  $-F$  and  $-F_1$  have  $-R_1$ . Moreover, we may readily show that  $R$  and  $-R_1$  are equal and

FIG. 35.

parallel, both being perpendicular to  $OO_1$ . The resultant of the two couples is, therefore, a couple whose arm is  $OO_1$  and force  $R$ , the diagonal of the parallelogram on  $F$  and  $F_1$ , so that

$$R = \sqrt{F^2 + F_1^2 + 2FF_1 \cos \theta},$$

where  $\theta$  is the angle between the planes of the couples. Now, if we draw from  $O$  the line  $Oa$  perpendicular to  $OO_1$  and to  $F_1$  and hence perpendicular to the plane of the first couple, and if we draw in the same manner  $Ob$  perpendicular to the plane of the second couple, so that there shall be in  $Oa$  as many units of length as there are units of moment in the first couple, and in  $Ob$  as many units of length as there are units of moment in the second couple, we shall have —

1°. The lines  $Oa$  and  $Ob$  are the moment axes of the two given couples respectively.

2°. The lines  $Oa$  and  $Ob$  lie in the same plane with  $F$  and  $F_1$ , this plane being perpendicular to  $OO_1$ .

3°. We have the proportion

$$Oa : Ob = F \cdot OO_1 : F_1 \cdot OO_1 = F : F_1.$$

4°. If on  $Oa$  and  $Ob$  as sides we construct a parallelogram, it will be similar to the parallelogram on  $F$  and  $F_1$ . We shall have the proportion

$$Oc : R = Oa : F = Ob : F_1;$$

and since the sides of the two parallelograms are respectively perpendicular to each other, the diagonals are perpendicular to each other; and since we have also

$$Oc = \frac{R \cdot Oa}{F} \quad \text{and} \quad Oa = F \cdot OO_1, \quad \therefore Oc = R \cdot OO_1,$$

it follows that  $Oc$  is perpendicular to the plane of the resultant couple, and contains as many units of length as there are units of moment in the moment of the resultant couple; in other

words,  $Oc$  will represent the *moment axis* of the resultant couple, and we shall have

$$Oc = \sqrt{Oa^2 + Ob^2 + 2Oa \cdot Ob \cos aOb};$$

or, if we let

$$Oa = L, \quad Ob = M, \quad Oc = G, \quad aOb = \theta,$$

$$G = \sqrt{L^2 + M^2 + 2LM \cos \theta}.$$

This determines the moment of the resultant couple; and, for the direction of its moment axis, we have

$$\sin aOc = \frac{M}{G} \sin \theta$$

and

$$\sin bOc = \frac{L}{G} \sin \theta.$$

Hence we can compound and resolve couples just as we do forces, provided we represent the couples by their *moment axes*

#### EXAMPLES.

1. Given  $L = 43$ ,  $M = 15$ ,  $\theta = 65^\circ$ ; find resultant couple.
2. Given  $L = 40$ ,  $M = 30$ ,  $\theta = 30^\circ$ ; find resultant couple.
3. Given  $L = 1$ ,  $M = 5$ ,  $\theta = 45^\circ$ ; find resultant couple.

§ 60. Resultant of a Couple and a Single Force in the Same Plane. — Let  $M$  (Fig. 36 or 37) be the moment of the

FIG. 36.

FIG. 37.

given couple, and let  $OF = F$  be the single force. For the given couple substitute an equivalent couple, one of whose forces is  $-F$  at  $O$ , equal and directly opposed to the single

force  $F$ , these two counterbalancing each other, and leaving only the other force of the couple, which is equal and parallel to the original single force  $F$ , and acts along a line whose distance from  $O$  is  $OA = \frac{M}{F}$ . Hence —

*The resultant of a single force and a couple in the same plane is a force equal and parallel to the original force, having its line of direction at a perpendicular distance from the original force equal to the moment of the couple divided by the force.*

Fig. 36 shows the case when the couple is right-handed, and Fig. 37 when it is left-handed.

§ 61. **Composition of Parallel Forces in General.** — In each case of composition of parallel forces (§§ 34, 35, and 36) it was stated that the method pursued was applicable to all cases except those where

$$\Sigma F = 0.$$

We were obliged, at that time, to reserve this case, because we had not studied the action of a statical couple; but now we will adopt a method for the composition of parallel forces which will apply in all cases.

(a) *When all the forces are in one plane.* Assume, as we did

FIG. 38.

in § 35, the axis  $OY$  to be parallel to the forces; assume the forces and the co-ordinates of their lines of direction, as shown in the figure (Fig. 38). Now place at the origin  $O$ , along  $OY$ , two equal and opposite forces, each equal to  $F_1$ ; then these three forces, viz.,  $F_1$  at  $D$ ,  $OA$ , and  $OB$ , produce the same effect as  $F_1$  at  $D$  alone; but  $F_1$  at  $D$  and  $OB$  form a couple (left-handed in the figure) whose moment is  $-F_1 x_1$ . Hence the

force  $F_1$  is equivalent to —

1°. An equal and parallel force at the origin, and

2°. A statical couple whose moment is  $-F_1x_1$ .

Likewise the force  $F_2$  is equivalent to (1°) an equal and parallel force at the origin, and (2°) a couple whose moment is  $-F_2x_2$ , etc.

Hence we shall have, if we proceed in the same way with all the forces, for resultant of the entire system a single force

$$R = \Sigma F \text{ along } OY,$$

and a single resultant couple

$$M = -\Sigma Fx.$$

(Observe that downward forces and left-handed couples are to be accounted negative.)

Now, there may arise two cases.

1°. When  $\Sigma F = 0$ , and

2°. When  $\Sigma F > 0$ .

CASE I. When  $\Sigma F = 0$ , the resultant force along  $OY$  vanishes, and the resultant of the entire system is a statical couple whose moment is

$$M = -\Sigma Fx.$$

CASE II. When  $\Sigma F > 0$ , we can reduce the resultant to a single force.

Let (Fig. 39)  $OB$  represent the resultant force along  $OY$ ,  $R = \Sigma F$ . With this, compound the couple whose moment is  $M = -\Sigma Fx$ , and we obtain as resultant (§ 60) a single force

$$R = \Sigma F,$$

FIG. 39.

whose line of action is at a perpendicular distance from  $OY$  equal to

$$AO = x_r = \frac{\Sigma Fx}{\Sigma F}.$$

(b) When the forces are not confined to one plane. Assume, as before (Fig. 40),  $OZ$  parallel to the forces, and let  $F$  acting

through  $A$  be one of the given forces, the co-ordinates of  $A$  being  $x$  and  $y$ . Place at  $O$  two equal and opposite forces, each equal to  $F$ , and also at  $B$  two equal and opposite forces, each equal to  $F$ . These five forces produce the same effect as  $F$  alone at  $A$ , and they may be considered to consist of—

- 1°. A single force  $F$  at the origin.
- 2°. A couple whose forces are  $F$  at  $B$  and  $-F$  at  $O$ , and whose moment is  $-Fx$  acting in the  $y$  plane.
- 3°. A couple whose forces are  $F$  at  $A$  and  $-F$  at  $B$ , and whose moment is  $Fy$  acting in the  $x$  plane. Treating each of the forces in the same way, we shall have, in place of the entire system of parallel forces, the following forces and couples:—

- 1°. A single force  $R = \Sigma F$  along  $OZ$ .
- 2°. A couple  $M_y = -\Sigma Fx$  in the  $y$  plane.
- 3°. A couple  $M_x = +\Sigma Fy$  in the  $x$  plane.

Now, there may be two cases:—

- 1°. When  $\Sigma F > 0$ .
- 2°. When  $\Sigma F = 0$ .

CASE I. When  $\Sigma F > 0$ , we can reduce to a single resultant force having a fixed line of direction. Lay off (Fig. 41) along  $OZ$ ,  $OH = \Sigma F$ .

Combining this with the first of the above-stated couples, we

obtain a force  $R = \Sigma F$  at  $A$ , where  $OA = \frac{\Sigma Fx}{\Sigma F} = x_r$ . Then combine with this resultant force  $R = \Sigma F$  at  $A$ , the second couple, and we shall have as single resultant of the entire system a single force

$$R = \Sigma F$$

acting through  $B$ , where

$$AB = y_r = \frac{\Sigma Fy}{\Sigma F}.$$

Hence the resultant is a force whose magnitude is

$$R = \Sigma F,$$

the co-ordinates of its line of direction being

$$x_r = \frac{\Sigma Fx}{\Sigma F}, \quad y_r = \frac{\Sigma Fy}{\Sigma F}.$$

CASE II. When  $\Sigma F = 0$ , there is no single resultant force; but the system reduces to two couples, one in the  $x$  plane and one in the  $y$  plane, and these two can be reduced to one single resultant couple. (Observe that couples are to be accounted positive when, on being looked at by the observer from the positive part of the axis towards the origin, they are right-handed; otherwise they are negative.)

The moment axis of the couple in the  $x$  plane will be laid off on the axis  $OX$  from the origin towards the positive side if the moment is positive, or towards the negative side if it is negative, and likewise for the  $y$  plane.

**FIG. 42.**

Hence lay off (Fig. 42)  $OB = M_x$ ,  $OA = M_y$ , and by completing the rectangle we shall have  $OD$  as the moment axis of the resultant couple; hence the resultant couple lies in a plane perpendicular to  $OD$ , and its moment bears to  $OD$  the same ratio as  $M_x$  bears to  $OB$ .

Hence we may write

$$OD = M_r = \sqrt{M_x^2 + M_y^2},$$

$$\cos DOX = \frac{M_x}{M_r} = \cos \theta.$$

If  $M_y$  had been negative, we should have  $OE$  as the moment axis of the resultant couple.

#### EXAMPLES.

|    | <i>F.</i> | <i>x.</i> | <i>y.</i> |    | <i>F.</i> | <i>x.</i> | <i>y.</i> |
|----|-----------|-----------|-----------|----|-----------|-----------|-----------|
| 1. | 5         | 4         | 3         | 2. | 5         | -4        | 3         |
|    | 3         | 2         | 1         |    | -2        | 2         | -1        |
|    | 1         | 3         | 5         |    | -3        | 3         | 5         |

Find the resultant in each example.

#### § 62. Resultant of any System of Forces acting at Different Points of a Rigid

Body, all situated in One Plane. — Let  $CF = F$  (Fig. 43) be one of the given forces.

Let all the forces be referred to a system of rectangular axes, as in the figure, and let  $\alpha$  = angle made by  $F$  with  $OX$ , etc. Let the co-ordinates of the point of application of  $F$  be  $AO = x$ ,  $BO = y$ .

FIG. 43.

Let the co-ordinates of the point of application of  $F$  be  $AO = x$ ,  $BO = y$ .

We first decompose  $CF = F$  into two components, parallel respectively to  $OX$  and  $OY$ . These components are

$$CD = F \cos \alpha, \quad CE = F \sin \alpha.$$

Apply at  $O$  in the line  $OY$  two equal and opposite forces, each equal to  $F \sin \alpha$ , and at  $O$  in the line  $OX$  two equal and opposite forces, each equal to  $F \cos \alpha$ . Since these four are mutually balanced, they do not alter the effect of the single force; and hence we have, in place of  $F$  at  $C$ , the six forces  $CD, OM, OK, CE, ON, OG$ . Of these six,  $CE$  and  $OG$  form a couple whose moment is

$$-(F \sin \alpha)x = -Fx \sin \alpha,$$

$CD$  and  $OK$  form a couple whose moment is

$$(F \cos \alpha)y = Fy \cos \alpha.$$

These two couples, being in the same plane, give as resultant moment their algebraic sum, or

$$F(y \cos \alpha - x \sin \alpha).$$

We have, therefore, instead of the single force at  $C$ , the following:—

1°.  $OM = F \cos \alpha$  along  $OX$ .

2°.  $ON = F \sin \alpha$  along  $OY$ .

3°. The couple  $M = F(y \cos \alpha - x \sin \alpha)$  in the given plane.

Decompose in the same way each of the given forces; and we have, on uniting the components along  $OX$ , those along  $OY$ , and the statical couples respectively, the following:—

1°. A resultant force along  $OX$ ,  $R_x = \Sigma F \cos \alpha$ .

2°. A resultant force along  $OY$ ,  $R_y = \Sigma F \sin \alpha$ .

3°. A resultant couple in the plane, whose moment is

$$M = \Sigma F(y \cos \alpha - x \sin \alpha).$$

This entire system, on compounding the two forces at  $O$ , reduces to

$$1^{\circ}. \quad R = \sqrt{R_x^2 + R_y^2} = \sqrt{(\Sigma F \cos \alpha)^2 + (\Sigma F \sin \alpha)^2};$$

making with  $OX$  an angle  $\alpha_r$ , where

$$\cos \alpha_r = \frac{\Sigma F \cos \alpha}{R}.$$

2°. A resultant couple in the same plane, whose moment is

$$M = \Sigma F(y \cos \alpha - x \sin \alpha).$$

Now compound this resultant force and couple, and we have,

for final resultant, a single force equal and parallel to  $R$ , and acting along a line whose perpendicular distance from  $O$  is equal to

$$\frac{M}{R}.$$

FIG. 44.

The equation of this line may be found as follows:

Suppose (Fig. 44) the force

$$OB = \Sigma F \cos \alpha,$$

$$OA = \Sigma F \sin \alpha,$$

$$OR = \sqrt{(\Sigma F \cos \alpha)^2 + (\Sigma F \sin \alpha)^2};$$

and let us suppose the resultant couple to be right-handed, and let

$$OM = \frac{M}{R};$$

then will the line  $ME$  parallel to  $OR$  be the line of direction of the single resultant force.

Assuming the force  $R$  to act at any point  $C(x_r, y_r)$  of this line, if we decompose it in the same way as we did the single forces previously, we obtain —

1°. The force  $R \cos \alpha_r = \Sigma F \cos \alpha$  along  $OX$ .

2°. The force  $R \sin \alpha_r = \Sigma F \sin \alpha$  along  $OY$ .

3°. The couple  $R(y_r \cos \alpha_r - x_r \sin \alpha_r)$ .

Hence we must have

$$R(y_r \cos \alpha_r - x_r \sin \alpha_r) = \Sigma F(y \cos \alpha - x \sin \alpha) = M.$$

Hence for the equation of the line of direction we have

$$y_r \cos \alpha_r - x_r \sin \alpha_r = \frac{M}{R}. \quad (1)$$

Another form for the same equation is

$$y_r(\Sigma F \cos \alpha) - x_r(\Sigma F \sin \alpha) = M. \quad (2)$$

§ 63. **Conditions of Equilibrium.** — If such a set of forces be in equilibrium, there must evidently be no tendency to translation and none to rotation. Hence we must have

$$R = 0 \quad \text{and} \quad M = 0.$$

Hence the conditions of equilibrium for any system of forces in a plane are three; viz., —

$$\Sigma F \cos \alpha = 0, \quad \Sigma F \sin \alpha = 0, \quad \Sigma F(y \cos \alpha - x \sin \alpha) = 0.$$

Another and a very convenient way to state the conditions of equilibrium for this case is as follows:—

*If the forces be resolved into components along two directions at right angles to each other, then the algebraic sum of the components along each of these directions must be zero, and the algebraic sum of the moments of the forces about any axis perpendicular to the plane of the forces must equal zero.*

## EXAMPLES.

1. Given  $\left\{ \begin{array}{cccc} F. & x. & y. & a. \\ 5 & 3 & 2 & 31^\circ \\ 10 & 1 & 3 & 40^\circ \\ -7 & 4 & 2 & 54^\circ \end{array} \right\}$  Find the resultant, and the equation of its line of direction.

2. Given  $\left\{ \begin{array}{cccc} F. & x. & y. & a. \\ 12 & 27 & 3 & 15^\circ \\ 4 & 13 & -5 & 30^\circ \\ 8 & -5 & -4 & 45^\circ \end{array} \right\}$  Find the resultant, and the equation of its line of direction.

§ 64. Resultant of any System of Forces not confined to One Plane. — Suppose we

FIG. 45.

have a number of forces applied at different points of a rigid body, and acting in different directions, of which we wish to find the resultant. Refer them all to a system of three rectangular axes,  $OX$ ,  $OY$ ,  $OZ$  (Fig. 45). Let  $PR = F$  be one of the given forces. Resolve it into three components,  $PK$ ,  $PH$ , and  $PG$ , parallel

respectively to the three axes. Let

$$RPK = \alpha, \quad RPH = \beta, \quad RPG = \gamma.$$

Let  $OA = x$ ,  $OB = y$ ,  $OC = z$ , be the co-ordinates of the point of application of the force  $F$ . Now introduce at  $B$  and also at  $O$  two forces, opposite in direction, and each equal to  $PK$ . We now have, instead of the force  $PK$ , the five forces  $PK$ ,  $BM$ ,  $BN$ ,  $OS$ , and  $OT$ . The two forces  $PK$  and  $BN$  form a couple in the  $y$  plane, whose axis is a line parallel to the axis  $OY$ , and whose moment is  $(PK)(EB) = (F \cos \alpha)z = Fz \cos \alpha$ . The

forces  $BM$  and  $OT$  form a couple in the  $z$  plane, whose moment is

$$(BM)(OB) = -Fy \cos \alpha.$$

Now do the same for the other forces  $PH$  and  $PG$ , and we shall finally have, instead of the force  $PR$ , three forces,

$$F \cos \alpha, \quad F \cos \beta, \quad F \cos \gamma,$$

acting at  $O$  in the directions  $OX$ ,  $OY$ , and  $OZ$  respectively, together with six couples, two of which are in the  $x$  plane, two in the  $y$  plane, and two in the  $z$  plane.

They thus form three couples, whose moments are as follows:—

$$\text{Around } OX, F(y \cos \gamma - z \cos \beta);$$

$$\text{Around } OY, F(z \cos \alpha - x \cos \gamma);$$

$$\text{Around } OZ, F(x \cos \beta - y \cos \alpha).$$

Treat each of the given forces in the same way, and we shall have, in place of all the forces of the system, three forces,

$$\Sigma F \cos \alpha \text{ along } OX,$$

$$\Sigma F \cos \beta \text{ along } OY,$$

$$\Sigma F \cos \gamma \text{ along } OZ;$$

and three couples, whose moments are as follows:—

$$\text{Around } OX, M_x = \Sigma F(y \cos \gamma - z \cos \beta);$$

$$\text{Around } OY, M_y = \Sigma F(z \cos \alpha - x \cos \gamma);$$

$$\text{Around } OZ, M_z = \Sigma F(x \cos \beta - y \cos \alpha).$$

The three forces give a resultant at  $O$  equal to

$$R = \sqrt{(\Sigma F \cos \alpha)^2 + (\Sigma F \cos \beta)^2 + (\Sigma F \cos \gamma)^2}, \quad (1)$$

$$\cos \alpha_r = \frac{\Sigma F \cos \alpha}{R}, \quad \cos \beta_r = \frac{\Sigma F \cos \beta}{R}, \quad \cos \gamma_r = \frac{\Sigma F \cos \gamma}{R}. \quad (2)$$

For the three couples we have as resultant

$$M = \sqrt{M_x^2 + M_y^2 + M_z^2}, \quad (3)$$

$$\cos \lambda = \frac{M_x}{M}, \quad \cos \mu = \frac{M_y}{M}, \quad \cos \nu = \frac{M_z}{M}; \quad (4)$$

$\lambda$ ,  $\mu$ , and  $\nu$  being the angles made by the moment axis of the resultant couple with  $OX$ ,  $OY$ , and  $OZ$  respectively.

*Thus far we have reduced the whole system to a single resultant force at the origin, and a couple.* Sometimes we can reduce

the system still farther, and sometimes not. The following investigation will show when we can do so. Let (Fig. 46)  $OP = R$  be the resultant force, and  $OC = M$  the moment axis of the resultant couple. Denote the angle between them by  $\theta$  (a quantity thus far undetermined). Project  $OP = R$  on  $OC$ . Its

FIG. 46.

projection will be  $OD = R \cos \theta$ ; then project, in its stead, the broken line  $OABP$  on  $OC$ . By the principles of projections, the projection of this broken line will equal  $OD$ .

Now  $OA$ ,  $AB$ , and  $BP$  are the co-ordinates of  $P$ , and make with  $OC$  the same angle as the axes  $OX$ ,  $OY$ , and  $OZ$ ; i.e.,  $\lambda$ ,  $\mu$ , and  $\nu$  respectively: hence the length of the projection is

$$OA \cos \lambda + AB \cos \mu + BP \cos \nu.$$

But

$$OA = R \cos \alpha_r, \quad AB = R \cos \beta_r, \quad BP = R \cos \gamma_r.$$

Hence

$$R \cos \theta = R \cos \alpha_r \cos \lambda + R \cos \beta_r \cos \mu + R \cos \gamma_r \cos \nu$$

$$\therefore \cos \theta = \cos \alpha_r \cos \lambda + \cos \beta_r \cos \mu + \cos \gamma_r \cos \nu. \quad (5)$$

This enables us to find the angle between the resultant force and the moment axis of the resultant couple.

The following cases may arise :—

1°. When  $\cos \theta = 0$ , or  $\theta = 90^\circ$ , the force lies in the plane of the couple, and we can reduce to a single force acting at a distance from  $O$  equal to  $\frac{M}{R}$ , and parallel to  $R$  at  $O$ .

2°. When  $\cos \theta = 1$ , or  $\theta = 0$ , the moment axis of the couple coincides in direction with the force: hence the plane of the couple is perpendicular to the force, and no farther reduction is possible.

3°. When  $\theta$  is neither  $0^\circ$  nor  $90^\circ$ , we can resolve the couple  $M$  into two component couples, one of which,  $M \cos \theta$ , acts in a plane perpendicular to the direction of  $R$ , and the other,  $M \sin \theta$ , acts in a plane containing  $R$ . The latter, on being combined with the force  $R$  at the origin, gives an equal and parallel force whose line of action is at a distance from that of  $R$  at  $O$ , equal to

$$\frac{M \sin \theta}{R}.$$

4°. When  $M = 0$ , the resultant is a single force at  $O$ .

5°. When  $R = 0$ , the resultant is a couple.

§ 65. **Conditions of Equilibrium.**—To produce equilibrium, we must have no tendency to translation and none to rotation. Hence we must have

$$R = 0 \quad \text{and} \quad M = 0.$$

Hence we have, in general, six conditions of equilibrium; viz.,—

$$\Sigma F \cos \alpha = 0, \quad \Sigma F \cos \beta = 0, \quad \Sigma F \cos \gamma = 0.$$

$$M_x = 0, \quad M_y = 0, \quad M_z = 0.$$

---

**EXAMPLES.**

1. Prove that, whenever three forces balance each other, they must lie in one plane.

2. Show how to resolve a given force into two whose sum is given.

3. A straight rod of uniform section and material is suspended by two strings attached to its ends, the strings being of given length, and attached to the same fixed point: find the position of equilibrium of the rod.

4. Two spheres are supported by strings attached to a given point, and rest against each other: find the tensions of the strings.

5. A straight rod of uniform section and material has its ends resting against two inclined planes at right angles to each other, the vertical plane which passes through the rod being at right angles to the line of intersection of the two planes: find the position of equilibrium of the rod, and the pressure on each plane, disregarding friction.

6. A certain body weighs 8 lbs. when placed in one pan of a false balance of equal arms, and 10 lbs. in the other: find the true weight of the body.

7. The points of attachment of the three legs of a three-legged table are the vertices of an isosceles right-angled triangle; a weight of 100 lbs. is supported at the middle of a line joining the vertex of one of the acute angles with the middle of the opposite side: find the pressure upon each leg.

8. A heavy body rests upon an inclined plane without friction: find the horizontal force necessary to apply, to prevent it from falling.

9. A rectangular picture is supported by a string passing over a smooth peg, the string being attached in the usual way at the sides, but one-fourth the distance from the top: find how many and what are the positions of equilibrium, assuming the absence of friction.

10. Two equal and weightless rods are jointed together, and form a right angle; they move freely about their common point: find the ratio of the weights that must be suspended from their extremities, that one of them may be inclined to the horizon at sixty degrees.

11. A weight of 100 lbs. is suspended by two flexible strings, one of which is horizontal, and the other is inclined at an angle of thirty degrees to the vertical: find the tension in each string.

## CHAPTER II.

## DYNAMICS.

§ 66. **Definitions.** — *Dynamics* is that part of mechanics which discusses the forces acting, when motion is the result.

*Velocity*, in the case of uniform motion, is the space passed over by the moving body in a unit of time; so that, if  $s$  represent the space passed over in time  $t$ , and  $v$  represent the velocity, then

$$v = \frac{s}{t}$$

*Velocity*, in variable motion, is the limit of the ratio of the space ( $\Delta s$ ) passed over in a short time ( $\Delta t$ ), to the time, as the latter approaches zero: hence

$$v = \frac{ds}{dt}$$

*Acceleration* is the limit of the ratio of the velocity ( $\Delta v$ ) imparted to the moving body in a short time ( $\Delta t$ ), to the time, as the time approaches zero. Hence, if  $a$  represent the acceleration,

$$a = \frac{dv}{dt} = \frac{d\left(\frac{ds}{dt}\right)}{dt} = \frac{d^2s}{dt^2}.$$

§ 67. **Uniform Motion.** — In this case the acceleration is zero, and the velocity is constant; and we have the equation

$$s = vt.$$

§ 68. **Uniformly Varying Motion.** — In this case the acceleration is constant: hence  $a$  is a constant in the equation

$$\frac{d^2s}{dt^2} = a,$$

and we obtain by one integration

$$v = \frac{ds}{dt} = at + c,$$

where  $c$  is an arbitrary constant: to determine it we observe, that, if  $v_0$  represent the value of  $v$  when  $t = 0$ , we shall have

$$v_0 = 0 + c$$

$$\therefore c = v_0$$

$$\therefore v = \frac{ds}{dt} = at + v_0$$

and by another integration

$$s = \frac{1}{2}at^2 + v_0t,$$

where  $s$  is the space passed over in time  $t$ ; the arbitrary constant vanishing, because, when  $t = 0$ ,  $s$  is also zero.

§ 69. **Measure of Force.** — It has already been seen, that, when a body is either at rest or moving uniformly in a straight line, there are either no forces acting upon it, or else the forces acting upon it are balanced. If, on the other hand, the motion of the body is rectilinear, but not uniform, the only unbalanced force acting is in the direction of the motion, and equal in magnitude to the momentum imparted in a unit of time in the direction of the motion, or, in other words, to the limit of the ratio of the momentum imparted in a short time ( $\Delta t$ ), to the time, as the latter approaches zero.

Thus, if  $F$  denote the force acting in the direction of the motion,  $m$  the mass, and  $a$  the acceleration, we shall have

$$F = ma = m \frac{dv}{dt} = m \frac{d^2s}{dt^2}. \quad (1)$$

From (1) we derive

$$m dv = F dt; \quad (2)$$

and, if  $v_0$  be the velocity of the moving body at the time when  $t = t_0$ , and  $v_1$  its velocity when  $t = t_1$ , we shall have

$$\int_{v_0}^{v_1} m dv = \int_{t_0}^{t_1} F dt$$

or

$$m(v_1 - v_0) = \int_{t_0}^{t_1} F dt; \quad (3)$$

or, in words, the momentum imparted to the body during the time  $t = (t_1 - t_0)$  by the force  $F$ , will be found by integrating the quantity  $F dt$  between the limits  $t_1$  and  $t_0$ .

**§ 70. Mechanical Work.** — Whenever a force is applied to a moving body, the force is either used in overcoming resistances (i.e., opposing forces, such as gravity or friction), and leaving the body free to continue its original motion undisturbed, or else it has its effect in altering the velocity of the body. In either case, the work done by the force is the product of the force, by the space passed through by the body in the direction of the force.

*Unit of Work.* — The unit of work is that work which is done when a unit of force acts through a unit of distance in the same direction as the force; thus, if one pound and one foot are our units of force and length respectively, the unit of work will be one foot-pound.

If a constant force act upon a moving body in the direction of its motion while the body moves through the space  $s$ , the work done by the force is

$$Fs;$$

and this, if the force is unresisted, is the energy, or capacity for performing work, which is imparted to the body upon which the force acts while it moves through the space  $s$ .

Thus, if a 10-pound weight fall freely through a height of 5 feet, the energy imparted to it by the force of gravity during this fall is  $10 \times 5 = 50$  foot-pounds, and it would be necessary to do upon it 50 foot-pounds of work in order to destroy the velocity acquired by it during its fall. If, on the other hand, the force is a variable, the amount of work done in passing over any finite space in its own direction will be found by integrating, between the proper limits, the expression

$$\int Fds.$$

*The power* which a machine exerts is the work which it performs in a unit of time.

*The unit of power* commonly employed is the *horse-power*, which in English units is equal to 33000 foot-pounds per minute, or 550 foot-pounds per second.

§ 71. **Energy.** — The energy of a body is its capacity for performing work.

*Kinetic or Actual Energy* is the energy which a body possesses in virtue of its velocity; in other words, it is the work necessary to be done upon the body in order to destroy its velocity. This is equal to the work which would have to be done to bring the body from a state of rest to the velocity with which it is moving. Assume a body whose mass is  $m$ , and suppose that its velocity has been changed from  $v_0$  to  $v_1$ . Then if  $F$  be the force acting in the direction of the motion, we shall have, from equation (2), § 69, that

$$Fvdt = mv dv; \quad (1)$$

but

$$vdt = ds$$

$$\therefore Fds = mv dv. \quad (2)$$

Hence, by integration,

$$\int_{v_0}^{v_1} mv dv = \int F ds$$

$$\therefore \frac{1}{2}m(v_1^2 - v_0^2) = \int F ds; \quad (3)$$

but  $\int F ds$  is the work that has been done on the body by the force, and the result of doing this work has been to increase its velocity from  $v_0$  to  $v_1$ . It follows, that, in order to change the velocity from  $v_0$  to  $v_1$ , the amount of work necessary to perform upon the body is

$$\frac{1}{2}m(v_1^2 - v_0^2) = \frac{1}{2} \frac{W}{g}(v_1^2 - v_0^2). \quad (4)$$

If  $v_0 = 0$ , this expression becomes

$$\frac{1}{2}mv_1^2, \text{ or } \frac{Wv_1^2}{2g}, \quad (5)$$

which is the expression for the kinetic energy of a body of mass  $m$  moving with a velocity  $v_1$ .

§ 72. **Atwood's Machine.** — A particular case of uniformly accelerated motion is to be found in Atwood's machine, in which a cord is passed over a pulley, and is loaded with unequal weights on the two sides. Were the weights equal, there would be no unbalanced force acting, and no motion would ensue; but when they are unequal, we obtain as a result a uniformly accelerated motion (if we disregard the action of the pulley), because we have a constant force equal to the difference of the two weights acting on a mass whose weight is the sum of the two weights. Thus, if we have a 10-pound weight on one side and a 5-pound weight on the other, the unbalanced force acting is

$$F = 10 - 5 = 5 \text{ lbs.}$$

The mass moved is  $M = \frac{10 + 5}{g}$ : hence the resulting acceleration is

$$a = \frac{5}{\left(\frac{15}{g}\right)} = \frac{g}{3}.$$

**§ 73. Normal and Tangential Components of the Forces acting on a Heavy Particle.** — If a body be in motion, either in a straight or in a curved line, and if at a certain instant all forces cease acting on it, the body will continue to move at a uniform rate in a straight line tangent to its path at that point where the body was situated when the forces ceased acting.

If an unresisted force be applied in the direction of the body's motion, the motion will still take place in the same straight line; but the velocity will vary as long as the force acts, and, from what we have seen, the equation

$$F = m \frac{d^2s}{dt^2} \quad (1)$$

will hold.

If an unresisted force act in a direction inclined to the body's motion, it will cause the body to change its speed, and also its course, and hence to move in a curved line. Indeed, if a force acting on a body which is in motion be resolved into two components, one of which is tangent to its path and the other normal, the tangential component will cause the body to change its speed, and the normal component will cause it to change the direction of its motion.

The measure of the tangential component is, as we have seen,

$$F = m \frac{d^2s}{dt^2};$$

and we will proceed to find an expression for the normal component otherwise known as the *Deviating Force*. For this

purpose we may substitute, for a small portion of the curve, a portion of the circle of curvature; hence we will proceed to find an expression for the centrifugal force of a body which moves uniformly with a velocity  $v$  in a circle whose radius is  $r$ .

## CENTRIFUGAL FORCE.

Let  $AC$  (Fig. 47) be the space described in the time  $\Delta t$ . Then we have

$$AC = v\Delta t.$$

The motion  $AC$  may be approximately considered as the result of a uniform motion

$$AB = v\Delta t \text{ nearly,}$$

and a uniformly accelerated motion

$$BC = \frac{1}{2}a(\Delta t)^2 = s,$$

where  $a$  = acceleration due to centrifugal force. But

$$(AB)^2 = BC \cdot BD,$$

or

$$(v\Delta t)^2 = \frac{1}{2}a(\Delta t)^2(2r + s),$$

where

$$AO = OC = r$$

$$\therefore v^2 = \frac{1}{2}a(2r + s) \text{ approximately}$$

$$\therefore a = \frac{2v^2}{2r + s} \text{ approximately.}$$

For its true value, pass to the limit where  $s = 0$ .

Hence we have, for the acceleration due to the centrifugal force, the expression

$$\frac{v^2}{r}.$$

Hence the centrifugal force is equal to

$$F = \frac{mv^2}{r} = \frac{Wv^2}{gr}. \quad (2)$$

FIG. 47.

## DEVIATING FORCE.

If a body is moving in a curved path, whether circular or not, and the unbalanced force acting on it be resolved into tangential and normal components, the tangential component will be, as has already been seen,

$$m \frac{d^2 s}{dt^2};$$

and the normal component will be

$$\frac{mv^2}{r} = \frac{m}{r} \left( \frac{ds}{dt} \right)^2,$$

where  $r$  is the radius of curvature of the path at the point in question.

## RESULTANT FORCE.

Hence it follows that the entire unbalanced force acting on the body will be

$$F = \sqrt{\left( m \frac{d^2 s}{dt^2} \right)^2 + \left( \frac{m}{r} \frac{ds^2}{dt^2} \right)^2},$$

or

$$F = m \sqrt{\left( \frac{d^2 s}{dt^2} \right)^2 + \frac{1}{r^2} \left( \frac{ds}{dt} \right)^4}. \quad (3)$$

§ 74. **Components along Three Rectangular Axes of the Velocities of, and of the Forces acting on, a Moving Body.**—If we resolve the velocity  $\frac{ds}{dt}$  into three components along  $OX$ ,  $OY$ , and  $OZ$ , we shall have, for these components respectively,

$$\frac{dx}{dt}, \quad \frac{dy}{dt}, \quad \text{and} \quad \frac{dz}{dt};$$

this being evident from the fact that  $dx$ ,  $dy$ , and  $dz$  are respec-

tively the projections of  $ds$  on the axes  $OX$ ,  $OY$ , and  $OZ$ ; and, from the differential calculus, we have

$$\frac{ds}{dt} = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2}.$$

On the other hand,

$$\frac{dx}{dt}, \quad \frac{dy}{dt}, \quad \text{and} \quad \frac{dz}{dt}$$

are not only the components of the velocity  $\frac{ds}{dt}$  in the directions  $OX$ ,  $OY$ , and  $OZ$ , but they are also the velocities of the body in these directions respectively.

Now, the case of the accelerations is different; for, while

$$\frac{d^2x}{dt^2}, \quad \frac{d^2y}{dt^2}, \quad \text{and} \quad \frac{d^2z}{dt^2}$$

are the accelerations in the directions  $OX$ ,  $OY$ , and  $OZ$  respectively, they are not the components of the acceleration

$$\frac{d^2s}{dt^2}$$

along the three axes.

That they are the former is evident from the fact that  $\frac{dx}{dt}$ ,  $\frac{dy}{dt}$ , and  $\frac{dz}{dt}$  are the velocities in the directions of the axes, and  $\frac{d^2x}{dt^2}$ ,  $\frac{d^2y}{dt^2}$ ,  $\frac{d^2z}{dt^2}$  are their differential co-efficients, and hence represent the accelerations along the three axes. But if we consider the components of the force acting on the body, we shall have

for its components along  $OX$ ,  $OY$ , and  $OZ$ , if  $\alpha$ ,  $\beta$ , and  $\gamma$  are the angles made by  $F$  with the axes respectively,

$$F \cos \alpha = m \frac{d^2x}{dt^2}, \quad F \cos \beta = m \frac{d^2y}{dt^2}, \quad F \cos \gamma = m \frac{d^2z}{dt^2},$$

$$\therefore F = m \sqrt{\left(\frac{d^2x}{dt^2}\right)^2 + \left(\frac{d^2y}{dt^2}\right)^2 + \left(\frac{d^2z}{dt^2}\right)^2}; \quad (1)$$

and we found (§ 73) for  $F$ , the value

$$F = m \sqrt{\left(\frac{d^2s}{dt^2}\right)^2 + \frac{1}{r^2} \left(\frac{ds}{dt}\right)^4}. \quad (2)$$

Hence, equating these values of  $F$ , and simplifying, we shall have the equation

$$\left(\frac{d^2x}{dt^2}\right)^2 + \left(\frac{d^2y}{dt^2}\right)^2 + \left(\frac{d^2z}{dt^2}\right)^2 = \left(\frac{d^2s}{dt^2}\right)^2 + \frac{1}{r^2} \left(\frac{ds}{dt}\right)^4$$

Hence it is plain that  $\frac{d^2x}{dt^2}$ ,  $\frac{d^2y}{dt^2}$ , and  $\frac{d^2z}{dt^2}$  can only be the components of the actual acceleration

$$\frac{d^2s}{dt^2}$$

when the last term  $\frac{1}{r^2} \left(\frac{ds}{dt}\right)^4$  vanishes, or when  $r = \infty$ , i.e., when the motion is rectilinear.

Moreover, we have the two expressions (1) and (2) for the force acting upon a moving body.

The truth of the proposition just proved may also be seen from the following considerations :—

If a parallelopiped be constructed with the edges

$$\frac{dx}{dt}, \quad \frac{dy}{dt}, \quad \frac{dz}{dt}$$

the diagonal will be the actual velocity

$$\frac{ds}{dt},$$

and will, of course, coincide in direction with its path.

On the other hand, if a parallelopiped be constructed with the edges

$$\frac{d^2x}{dt^2}, \quad \frac{d^2y}{dt^2}, \quad \frac{d^2z}{dt^2},$$

its diagonal must coincide in direction with the force

$$F = m\sqrt{\left(\frac{d^2s}{dt^2}\right)^2 + \frac{1}{r^2}\left(\frac{ds}{dt}\right)^4},$$

and can coincide in direction with the path, and hence with the actual acceleration

$$\frac{d^2s}{dt^2},$$

only when the force is tangential to the path, and hence when the motion is rectilinear.

**§ 75. Centrifugal Force of a Solid Body.** — When a solid body revolves in a circle, the resultant centrifugal force of the entire body acts in the direction of the perpendicular let fall from the centre of gravity of the body on the axis of rotation, and its magnitude is the same as if its entire weight were concentrated at its centre of gravity.

**PROOF.** — Let (Fig. 48) the angular velocity =  $\alpha$ , and the total weight =  $W$ . Assume the axis of rotation perpendicular to the plane of the paper and passing through  $O$ ; assume, as axis of  $x$ , the perpendicular dropped from the centre of gravity upon the axis of rotation. The co-ordinates of the centre of gravity will then be  $(x_0, y_0)$ , and  $y_0$  will be equal to zero.

FIG. 48.

If, now,  $P$  be any particle of weight  $w$ , where  $r$  = perpendicular distance from  $P$  on axis of rotation,

and  $x = OA$ ,  $y = AP$ , we shall have for the centrifugal force of the particle at  $P$

$$\frac{w}{g} a^2 r;$$

but if we resolve this into two components, parallel respectively to  $OX$  and  $OY$ , we shall have for these components

$$\left(\frac{w}{g} a^2 r\right) \frac{x}{r} = \frac{a^2}{g} wx \quad \text{and} \quad \left(\frac{w}{g} a^2 r\right) \frac{y}{r} = \frac{a^2}{g} wy,$$

and, for the resultant for the entire body we shall have, parallel to  $OX$ ,

$$F_x = \frac{a^2}{g} \sum wx = \frac{a^2}{g} Wx_o \quad (1)$$

and

$$F_y = \frac{a^2}{g} \sum wy = \frac{a^2}{g} Wy_o = 0. \quad (2)$$

Hence the centrifugal force of the entire body is

$$F = \frac{a^2}{g} Wx_o; \quad (3)$$

and if we let  $v_o = ax_o =$  linear velocity of the centre of gravity, we have

$$F = \frac{Wv_o^2}{gx_o},$$

which is the same as though the entire weight of the body were concentrated at its centre of gravity.

#### EXAMPLES.

1. A 10-pound weight is fastened by a rope 5 feet long to the centre, around which it revolves at the rate of 200 turns per minute; find the pull on the cord.

2. A locomotive weighing 50000 lbs., whose driving-wheels weigh 7000 lbs., is running at 60 miles per hour, the diameter of the drivers

being 6 feet, and the distance from the centre of the wheel to the centre of gravity of the same being 2 inches (the drivers not being properly balanced) ; find the pressure of the locomotive on the track ( $a$ ) when the centre of gravity is directly below the centre of the wheel, and ( $b$ ) when it is directly above.

3. Assume the same conditions, except that the distance between centre of the wheel and its centre of gravity is 5 inches instead of 2.

§ 76. **Uniformly Varying Rectilinear Motion.** — We have already found for this case (§ 68) the equations

$$\frac{d^2s}{dt^2} = a = \text{a constant},$$

$$\frac{ds}{dt} = v = v_0 + at,$$

$$s = v_0t + \frac{1}{2}at^2;$$

and we may write for the force acting, which is, of course, coincident in direction with the motion,

$$F = m \frac{d^2s}{dt^2} = ma = \text{a constant}.$$

§ 77. **Motion of a Body acted on by the Force of Gravity only.** — A useful special case of uniformly varying motion is that of a body moving under the action of gravity only.

The downward acceleration due to gravity is represented by  $g$  feet per second, the value of  $g$  varying at different points on the surface of the earth according to the following law :—

$$g = g_1(1 - 0.00284 \cos 2\lambda) \left(1 - \frac{2h}{R}\right) \text{ feet per second,}$$

where

$$g_1 = 32.1695 \text{ feet,}$$

$$\lambda = \text{latitude of the place,}$$

$$h = \text{its elevation above mean sea-level in feet,}$$

$$R = 20900000 \text{ feet.}$$

If, now, we represent by  $h$  the height fallen through by a descending body in time  $t$ , we shall have the equations,

$$\begin{aligned}v &= v_0 + gt, \\h &= v_0 t + \frac{1}{2}gt^2,\end{aligned}$$

where  $v_0$  is the initial downward velocity.

If, on the other hand, we represent by  $v_0$  the initial upward velocity, and by  $h$  the height to which the body will rise in time  $t$  under the action of gravity only, we must write the equations

$$\begin{aligned}v &= v_0 - gt, \\h &= v_0 t - \frac{1}{2}gt^2.\end{aligned}$$

When  $v_0 = 0$ , the first set of equations gives

$$\begin{aligned}v &= gt, \\h &= \frac{1}{2}gt^2,\end{aligned}$$

which express the law of motion of a body starting from rest and subject to the action of gravity only.

Eliminate  $t$  between these equations, and we shall have

$$v^2 = 2gh \quad \therefore v = \sqrt{2gh},$$

or

$$h = \frac{v^2}{2g}.$$

$h$  is called the *height due to the velocity*  $v$ , and represents the height through which a falling body must drop to acquire the velocity  $v$ ; and

$$v = \sqrt{2gh}$$

is the velocity which a falling body will acquire in falling through the height  $h$ . Thus, if a body fall through a height of 50 feet, it will, by that fall, acquire a velocity of about

$$\sqrt{2(32\frac{1}{2})(50)} = \sqrt{3216.66} = 56.7 \text{ feet per second.}$$

Again : if a body has a velocity of 40 feet per second, we shall have

$$h = \frac{v^2}{2g} = \frac{1600}{64.3} = 24.8 \text{ feet ;}$$

and we say that the body has a velocity due to the height 24.8 feet, i. e., a velocity which it would acquire by falling through a height of 24.8 feet.

#### EXAMPLES.

1. A stone is dropped down a precipice, and is heard to strike the bottom in 4 seconds after it started : how high is the precipice?

2. How long will a stone, dropped down a precipice 500 feet high, take to reach the bottom?

3. What will be its velocity just before striking the ground?

4. A body is thrown vertically upwards with a velocity of 100 feet per second ; to what height will it rise?

5. A body is thrown vertically upwards, and rises to a height of 50 feet. With what velocity was it thrown, and how long was it in its ascent?

6. What will be its velocity in its ascent at a point 15 feet above the point from which it started, and what at the same point in its descent?

§ 78. **Unresisted Projectile.** — In the case of an unresisted projectile, we have a body on which is impressed a uniform

motion in a certain direction (the direction of its initial motion), and which is acted on by the force of gravity only.

FIG. 49.

Let  $OPC$  be the path (Fig. 49),  $OA$  the initial direction, and  $v_0$  the initial velocity, and the angle  $AOX = \theta$ .

Then we shall have, for the horizontal and vertical components of the unbalanced force acting, when the projectile is at  $P$  (co-ordinates  $x$  and  $y$ ),

$$m \frac{d^2x}{dt^2} = 0 \text{ along } OX, \text{ and } m \frac{d^2y}{dt^2} = -mg = -W \text{ along } OY.$$

Hence

$$\frac{d^2x}{dt^2} = 0, \quad (1) \quad \frac{d^2y}{dt^2} = -g. \quad (2)$$

Integrating, and observing, that, when  $t = 0$ , the horizontal and the vertical velocities were respectively  $v_0 \cos \theta$  and  $v_0 \sin \theta$ , we have

$$\frac{dx}{dt} = v_0 \cos \theta, \quad (3)$$

$$\frac{dy}{dt} = v_0 \sin \theta - gt. \quad (4)$$

These equations could be derived directly by observing that the horizontal component of the initial velocity is  $v_0 \cos \theta$ , and that this remains constant, as there is no unbalanced force acting in this direction, also that  $v_0 \sin \theta$  is the initial vertical velocity; and, since the body is acted on by gravity only, this velocity will in time  $t$  be decreased by  $gt$ .

Integrating equations (3) and (4), and observing that for  $t = 0$ ,  $x$  and  $y$  are both zero, we obtain

$$x = v_0 \cos \theta \cdot t, \quad (5)$$

$$y = v_0 \sin \theta \cdot t - \frac{1}{2}gt^2. \quad (6)$$

Eliminate  $t$ , and we have

$$y = x \tan \theta - \frac{gx^2}{2v_0^2 \cos^2 \theta} \quad (7)$$

as the equation of the path, which is consequently a parabola.

Equations (1), (2), (3), (4), (5), (6), and (7) enable us to solve any problem with reference to an unresisted projectile.

Equation (7) may be written

$$\left(y - \frac{v_0^2 \sin^2 \theta}{2g}\right) = -\frac{g}{2v_0^2 \cos^2 \theta} \left(x - \frac{v_0^2 \sin \theta \cos \theta}{g}\right)^2 \quad (8)$$

which gives for the co-ordinates of the vertex

$$y_1 = \frac{v_0^2 \sin^2 \theta}{2g}, \quad x_1 = \frac{v_0^2 \sin \theta \cos \theta}{g}.$$

#### EXAMPLES.

1. An unresisted projectile starts with a velocity of 100 feet per second at an upward angle of  $30^\circ$  to the horizon; what will be its velocity when it has reached a point situated at a horizontal distance of 1000 feet from its starting-point, and how long will be required for it to reach that point?

*Solution.*

$$v_0 = 100, \quad \theta = 30^\circ, \quad v_0 \cos \theta = 86.6, \quad v_0 \sin \theta = 50, \\ g = 32.16.$$

Equation (5) gives us

$$1000 = 86.6 t$$

$$\therefore t = \frac{1000}{86.6} = 11.55 \text{ seconds.}$$

$$v_0 \sin \theta - gt = 50 - 371.5 = -321.5,$$

$$v = \sqrt{(86.6)^2 + (321.5)^2} = \sqrt{7500 + 103362} = 333.$$

Hence the point in question will be reached in  $11\frac{1}{2}$  seconds after starting, and the velocity will then be 333 feet per second.

2. An unresisted projectile is thrown upwards from the surface of the earth at angle of  $39^\circ$  to the horizontal: find the time when it will reach the earth, and the velocity it will have acquired when it reaches the earth, the velocity of throwing being 30 feet per second.

3. A 10-pound weight is dropped from the window of a car when travelling over a bridge at a speed of 25 miles an hour. How long will it take to reach the ground 100 feet below the window, and what will be the kinetic energy when it reaches the ground?

4. With what horizontal velocity, and in what direction, must it be thrown, in order that it may strike the ground 50 feet forward of the point of starting?

5. Suppose the same 10-pound weight to be thrown vertically upwards from the car window with a velocity of 100 feet a minute, how long will it take to reach the ground, and at what point will it strike the ground?

### § 79. Motion of a Body on an Inclined Plane without

FIG. 50.

**Friction.** — If a body move on an inclined plane along the line of steepest descent, subject to the action of gravity only, and if we resolve the force acting on it (i.e., its weight) into two components, along and perpendicular to the plane respectively, the latter component will be entirely balanced by the resistance of the plane,

and the former will be the only unbalanced force acting on the body.

Suppose a body whose weight is represented (Fig. 50) by  $HF = W$  to move along the inclined path  $AB$  under the action of gravity only. Let  $\theta$  be the inclination of  $AB$  to the horizon. Resolve  $W$  into two components,

$$HD = W \sin \theta, \quad \text{and} \quad HE = W \cos \theta,$$

respectively parallel and perpendicular to the plane. The former is the only unbalanced force acting on the body, and will cause it to move down the plane with a uniformly accelerated motion; the acceleration being

$$\frac{W \sin \theta}{\left(\frac{W}{g}\right)} = g \sin \theta. \quad (1)$$

If the body is either at rest or moving downwards at the beginning, it will move downwards; whereas, if it is first moving upwards, it will gradually lose velocity, and move upwards more slowly, until ultimately its upward velocity will be destroyed, and it will begin moving downwards.

The equations for uniformly varying motion are entirely applicable to these cases. Thus, suppose that the body has an initial downward velocity  $v_0$ , this velocity will, at the end of the time  $t$ , become

$$v = \frac{ds}{dt} = v_0 + (g \sin \theta)t \quad (2)$$

$$\therefore s = v_0 t + \frac{1}{2} g \sin \theta \cdot t^2, \quad (3)$$

and, for the unbalanced force acting, we have

$$F = m \frac{d^2 s}{dt^2} = \frac{W}{g} (g \sin \theta) = W \sin \theta. \quad (4)$$

If, on the other hand, the body's initial velocity is upward, and we denote this upward velocity by  $v_0$ , we shall have the equations

$$v = \frac{ds}{dt} = v_0 - (g \sin \theta)t \quad (5)$$

$$s = v_0 t - \frac{1}{2}g \sin \theta \cdot t^2 \quad (6)$$

$$F = -W \sin \theta. \quad (7)$$

Again, if the initial velocity is zero, equations (2) and (3) become

$$v = \frac{ds}{dt} = (g \sin \theta)t, \quad (8)$$

$$s = \frac{1}{2}g \sin \theta \cdot t^2. \quad (9)$$

From these we obtain, for this case,

$$t = \sqrt{\frac{2s}{g \sin \theta}}; \quad (10)$$

and, substituting this value of  $t$  in (8), we have

$$v = \sqrt{2g(s \sin \theta)}, \quad (11)$$

or, if we let  $s \sin \theta = h =$  the vertical distance through which the body has fallen, we have

$$v = \sqrt{2gh}. \quad (12)$$

Hence, *When a body, starting from rest, falls, under the action of gravity only, through a height  $h$ , the velocity acquired is  $\sqrt{2gh}$ , whether the path be vertical or inclined.*

#### EXAMPLES.

1. A body moves from the top to the bottom of a plane inclined to the horizon at  $30^\circ$ , under the action of gravity only: find the time required for the descent, and the velocity at the foot of the plane.

2. In the right-angled triangle shown in the figure (Fig. 51), given  $AB = 10$  feet, angle  $BAC = 30^\circ$ : find the time a body would require, if acted on by gravity only, to fall from rest through each of the sides respectively,  $AB$  being vertical.

3. Given inclination of plane to the horizon  $= \theta$ , length of plane  $= l$ : compare the time of falling down the plane with the time of falling down the vertical.

4. A 100-pound weight rests, without friction, on the plane of example 3. What horizontal force is required to keep it from sliding down the plane.

5. Suppose 5 pounds horizontal force to be applied (a) so as to oppose the descent, (b) so as to aid the descent: find in each case how long it will take the weight to descend from the top to the bottom plane.

FIG. 51.

§ 80. **Motion along a Curved Line under the Action of Gravity only.** — We shall consider two questions in this regard: (a) the velocity at any point of the curve (b) the time of descent through any part of the curve.

(a) *Velocity at any point.* Let us suppose the body to have started from rest at  $A$ , and to have reached the point  $P$  in time  $t$ , where  $AB = x$  (Fig. 52). Then, since the curved line  $AP$  may be considered as the limit of a broken line running from  $A$  to  $P$ , and as it has already been seen that the velocity acquired by falling through a certain height depends only upon the height, and not upon the inclination of the path, we shall have for a curved line also

FIG. 52.

$$v = \sqrt{2gAB} = \sqrt{2gx},$$

where  $v$  is the velocity at  $P$ .

(b) *Time down a curve.* Referring to the same figure, let  $t$  denote the time required to go from  $A$  to  $P$ , and  $\Delta t$  the time to go from  $P$  to  $P'$ , where  $PP' = \Delta s$ , and  $BB' = \Delta x$ ; then, as we have seen that the velocity at  $P$  is  $\sqrt{2gx}$ , we shall have approximately for the space passed over in time  $\Delta t$ , the equation

$$\Delta s = \sqrt{2gx} \Delta t,$$

or, passing to the limit,

$$\frac{ds}{dt} = \sqrt{2gx}. \quad (1)$$

This equation gives

$$dt = \frac{ds}{\sqrt{2gx}}$$

or

$$t = \int \frac{ds}{\sqrt{2gx}} = \int \frac{\sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx}{\sqrt{2gx}}, \quad (2)$$

where, of course, the proper limits of integration must be used.

If  $t$  denote the time from  $A$  to  $P$ , we have

$$t = \int_{x=0}^{x=x} \frac{ds}{\sqrt{2gx}}.$$

#### EXAMPLE.

FIG. 53.

A body acted on by gravity only is constrained to move in the arc of a circle from  $A$  to  $C$  (Fig. 53), radius 10 feet. Find the time of describing the arc (quadrant) and the velocity acquired by the body when it reaches

§ 81. **Simple Circular Pendulum.**—To find the time occupied in a vibration of a simple circular pendulum, we take  $D$  (Fig. 54) as origin, and  $DC$  as axis of  $x$ , and the axis of  $y$  at right angles to  $DC$ . Let  $AC = l$  and  $BD = h$ , we shall have for the time of a single oscillation from  $A$  to  $E$

$$t = 2 \int_{x=0}^{x=h} \frac{ds}{\sqrt{2g(h-x)}}$$

FIG. 54.

Now, from the equation of the circle  $AFDE$ ,

$$y^2 = 2lx - x^2,$$

we have

$$\frac{dy}{dx} = \frac{l-x}{y}$$

$$\therefore \frac{ds}{dx} = \frac{l}{y} = \frac{l}{\sqrt{2lx - x^2}}$$

$$\therefore t = 2 \int_0^h \frac{ldx}{\sqrt{(2lx - x^2)[2g(h-x)]}} = \frac{2l}{\sqrt{2g}} \int_0^h \frac{dx}{\sqrt{hx - x^2} \sqrt{2l - x}}$$

or

$$t = \sqrt{\frac{l}{g}} \int_0^h \frac{dx}{\sqrt{hx - x^2}} \left(1 - \frac{x}{2l}\right)^{-\frac{1}{2}}.$$

This can only be integrated approximately.

Expanding  $\left(1 - \frac{x}{2l}\right)^{-\frac{1}{2}}$  we obtain

$$\left(1 - \frac{x}{2l}\right)^{-\frac{1}{2}} = 1 + \frac{x}{4l} + \frac{3}{32} \frac{x^2}{l^2} + \text{etc.},$$

$$\therefore t = \sqrt{\frac{l}{g}} \int_0^h \left(1 + \frac{x}{4l} + \frac{3}{32} \frac{x^2}{l^2} + \text{etc.}\right) \frac{dx}{\sqrt{hx - x^2}}$$

The greatest value of  $x$  is  $h$ ; and if  $h$  is so small that we may omit  $\frac{x}{4l}$ , we shall have as our approximate result

$$t = \sqrt{\frac{l}{g}} \int_0^h \frac{dx}{\sqrt{hx - x^2}} = \sqrt{\frac{l}{g}} \left\{ \text{versin}^{-1} \frac{2x}{h} \right\}_0^h = \pi \sqrt{\frac{l}{g}}. \quad (1)$$

If, however, the value of  $h$  as compared with  $l$  is too large to render it sufficiently accurate to omit  $\frac{x}{4l}$ , but so small that we can safely omit the higher powers of  $\frac{x}{l}$ , we shall have

$$\begin{aligned} t &= \sqrt{\frac{l}{g}} \left\{ \text{versin}^{-1} \frac{2x}{h} + \frac{1}{4l} \int_0^h \frac{x dx}{\sqrt{hx - x^2}} \right\}_0^h \\ &= \sqrt{\frac{l}{g}} \left\{ \text{versin}^{-1} \frac{2x}{h} + \frac{1}{4l} \left[ \frac{h}{2} \text{versin}^{-1} \frac{2x}{h} - \sqrt{hx - x^2} \right] \right\}_0^h \end{aligned}$$

or

$$t = \pi \sqrt{\frac{l}{g}} \left( 1 + \frac{h}{8l} \right), \quad (2)$$

a nearer approximation.

The formula

$$t = \pi \sqrt{\frac{l}{g}}$$

is the most used, and is more nearly correct, the smaller the value of  $h$ .

#### EXAMPLES.

1. Find the length of the simple circular pendulum which is to beat seconds at a place where  $g = 32\frac{1}{8}$ .

*Solution.*

$$t = \pi \sqrt{\frac{l}{g}} \quad \therefore l = \frac{t^2 g}{\pi^2} = \frac{32\frac{1}{8}}{(3.1416)^2} = 3.259 \text{ feet.}$$

2. What is the time of vibration of a simple circular pendulum 5 feet long?

§ 82. **Simple Cycloidal Pendulum.** — The equation of the cycloid is

$$y = a \operatorname{versin}^{-1} \frac{x}{a} + (2ax - x^2)^{\frac{1}{2}},$$

$$\therefore \frac{dy}{dx} = \sqrt{\frac{2a-x}{x}}$$

$$\therefore \frac{ds}{dx} = \left(\frac{2a}{x}\right)^{\frac{1}{2}}.$$

Hence we shall have, for the time of a single oscillation,

$$t = 2 \frac{\sqrt{2a}}{\sqrt{2g}} \int_0^h \frac{dx}{\sqrt{hx - x^2}}$$

or

$$t = 2 \left(\frac{a}{g}\right)^{\frac{1}{2}} \left\{ \operatorname{versin}^{-1} \frac{2x}{h} \right\}_0^h = \pi \sqrt{\frac{a}{g}}.$$

This expression is independent of  $h$ , so that the time of vibration is the same whether the arc be large or small.

A body can be made to vibrate in a cycloidal arc by suspending it by a flexible string between two cycloidal cheeks. This is shown from the fact that the evolute of the cycloid is another cycloid (Fig. 55).

To prove this, we have, from the equation of the cycloid,

$$y = a \operatorname{versin}^{-1} \frac{x}{a} + (2ax - x^2)^{\frac{1}{2}},$$

$$\frac{dy}{dx} = \sqrt{\frac{2a-x}{x}}, \quad \frac{ds}{dx} = \sqrt{\frac{2a}{x}},$$

$$\frac{d^2y}{dx^2} = \frac{-a}{x^{\frac{3}{2}} \sqrt{2a-x}}$$

FIG. 55.

Hence the radius of curvature is

$$\rho = \frac{\left(\frac{ds}{dx}\right)^3}{-\frac{d^2y}{dx^2}} = (2)^{\frac{1}{2}}(a)^{\frac{1}{2}}\sqrt{2a-x}$$

or

$$\rho = 2(2a)^{\frac{1}{2}}\sqrt{2a-x};$$

and since we have for the evolute the relation

$$ds' = d\rho,$$

where  $ds'$  is the elementary arc of the evolute,

$$\therefore s' = \int_{x=2a}^{x=2a-x} d\rho;$$

and, observing that when  $x = 2a$   $\rho = 0$ , we have

$$\begin{aligned} s' &= \rho, \\ \therefore s' &= 2(2a)^{\frac{1}{2}}\sqrt{2a-x}; \end{aligned}$$

or, if we transform co-ordinates to  $B$  by putting  $x$  for  $2a - x$ , we obtain

$$\begin{aligned} s' &= 2(2ax)^{\frac{1}{2}}, \\ \therefore s'^2 &= 8ax, \end{aligned}$$

which is the equation of another cycloid just like the first.

The motion along a vertical cycloid may also be obtained by letting a body move along a groove in the form of a cycloid acted on by gravity alone; and in this case the time of descent of the body to the lowest point is precisely the same at whatever point of the curve the body is placed.

**§ 83. Effect of Grade on the Tractive Force of a Railway Train.**—As a useful particular case of motion on an inclined plane, we have the case of a railroad train moving up or down a grade. It is necessary that a certain tractive force

be exerted in order to overcome the resistances, and keep the train moving at a uniform rate along a level track. If, on the other hand, the track is not on a level, and if we resolve the weight of the train into components at right angles to and along the plane of the track, we shall have in the latter component a force which must be added to the tractive force above referred to when we wish to know the tractive force required to carry it up grade, and must be subtracted when we wish to know the tractive force required to carry it down grade. The result of this subtraction may give, if the grade is sufficiently steep and the speed sufficiently slow, a negative quantity; and in that case we must apply the brakes, instead of using steam, unless we wish the speed of the train to increase.

#### EXAMPLES.

1. A railroad train weighing 60000 lbs., and running at 50 miles per hour, requires a tractive force of 618 lbs. on a level; what is the tractive force necessary when it is to ascend a grade of 50 feet per mile? What when it is to descend? Also what is the amount of work per minute in each case?

#### Solution.

The resolution of the weight will give (Fig. 50, § 79), for the component along the plane,

$$(60000) \frac{50}{5280} = 568.2 \text{ nearly.}$$

Hence

$$\text{Tractive force for a level} = 618.0,$$

$$\text{Tractive force for ascent} = 1186.2,$$

$$\text{Tractive force for descent} = 49.8.$$

To ascertain the work done per minute in each case, we have—

$$(a) \text{ For a level track, } \frac{618 \times 50 \times 5280}{60} = 2719200 \text{ foot-lbs.}$$

$$(b) \text{ Up grade, } 2719200 + \frac{60000 \times 50 \times 50}{60} = 5219200 \text{ foot-lbs.}$$

$$(c) \text{ Down grade, } 2719200 - \frac{60000 \times 50 \times 50}{60} = 219200 \text{ foot-lbs.}$$

2. Suppose the tractive force required for each 2000 lbs. of weight of train to be, on a level track, for velocities of —

|                     |      |      |      |      |      |     |
|---------------------|------|------|------|------|------|-----|
| 5.0 miles per hour, | 10.0 | 20.0 | 30.0 | 40.0 | 50.0 | 60  |
| 6.1 lbs.,           | 6.6  | 8.3  | 11.2 | 15.3 | 20.6 | 27; |

find the tractive force required to carry the train of example 1 —

(a) Up an incline of 50 feet per mile at 30 miles per hour.

(b) Down an incline of 50 feet per mile at 30 miles per hour.

(c) Down an incline of 10 feet per mile at 20 miles per hour.

(d) What must be the incline down which the train must run to require no tractive force at 40 miles per hour?

3. If in the first example the tractive force remains 618 lbs. while the train is going down grade, what will be its velocity at the end of one minute, the grade being 10 feet per mile?

§ 84. **Harmonic Motion.**—If we imagine a body to be moving in a circle at a uniform rate (Fig. 56), and a second

FIG. 56.

body to oscillate back and forth in the diameter  $AB$ , both starting from  $B$ , and if when the first body is at  $C$  the other is directly under it at  $G$ , etc., then is the second body said to

move in harmonic motion.

A practical case of this kind of motion is the motion of a slotted cross-head of an engine, as shown in the figure (Fig. 57); the crank moving at a uniform rate. In the case of the ordinary crank, and connecting-rod connecting the drive-wheel shaft of a stationary engine with the piston-rod,

FIG. 57.

we have in the motion of the piston only an approximation to harmonic motion. We will proceed to determine the law of the force acting upon, and the velocity of, a body which is constrained to move in harmonic motion. Let the body itself and the corresponding revolving body be supposed to start from  $B$  (Fig. 56), the latter revolving in left-handed rotation with an angular velocity  $\alpha$ , and let the time taken by the former in reaching  $G$  be  $t$ : then will the angle  $BOC = \alpha t$ ; and we shall have, if  $s$  denote the space passed over by the body that moves with harmonic motion,

$$s = BG = OB - OC \cos \alpha t,$$

or, if

$$r = OB = OC,$$

$$s = r - r \cos \alpha t, \quad (1)$$

the velocity at the end of the time  $t$  will be

$$v = \frac{ds}{dt} = \alpha r \sin \alpha t, \quad (2)$$

and the acceleration at the end of time  $t$  will be

$$f = \frac{d^2s}{dt^2} = \alpha^2 r \cos \alpha t. \quad (3)$$

Hence the force acting upon the body at that instant, in the direction of its motion, is

$$F = m \frac{d^2s}{dt^2} = m \alpha^2 r \cos \alpha t = m \alpha^2 (OG). \quad (4)$$

The force, therefore, varies directly as the distance of the body from the centre of its path. It is zero when the body is at the

centre of its path, and greatest when it is at the ends of its travel, as its value is then

$$ma^2r = \frac{W}{g}a^2r;$$

this being the same in amount as the centrifugal force of the revolving body, provided this latter have the same weight as the oscillating body. On the other hand, the velocity is greatest when  $\omega t = \frac{\pi}{2}$  (i.e., at mid-stroke); and its value is then

$$v = ar,$$

this being also the velocity of the crank-pin at mid-stroke.

#### EXAMPLE.

Given that the reciprocating parts of an engine weigh 10000 lbs., the length of crank being 1 foot, the crank making 60 revolutions per minute; find the force required to make the cross-head follow the crank, (1) when the crank stands at  $30^\circ$  to the line of dead points, (2) when at  $60^\circ$ , (3) when at the dead point.

§ 85. **Work under Oblique Force.**—If the force act in any other direction than that of the motion, we must resolve it into two components, the component in the direction of the motion being the only one that does work. Thus if the force  $F$  is variable, and  $\theta$  equals the angle it makes with the direction of the motion, we shall have as our expression for the work done

$$\int F \cos \theta ds.$$

Thus if a constant force of 100 lbs. act upon a body in a direction making an angle of  $30^\circ$  with the line of motion, then will the work done by the force during the time in which it moves through a distance of 10 feet be

$$(100)(0.86603)(10) = 866 \text{ foot-lbs.}$$

§ 86. **Rotation of Rigid Bodies.**— Suppose a rigid body (Fig. 58) to revolve about an axis perpendicular to the plane of the paper, and passing through  $O$ ; imagine a particle whose weight is  $w$  to be situated at a perpendicular distance  $OA = r$  from the axis of rotation, and let the angular velocity be  $\alpha$ : let it now be required to find the moment of the force or forces required to impart this motion in a unit of time; for we know, that, if the axis of rotation pass through the centre of gravity of the body, the motion can be imparted only by a statical couple; whereas if it do not pass through the centre of gravity, the motion can be imparted by a single force.

FIG. 58.

We shall have, for the particle situated at  $A$ ,

Weight =  $w$ .

Angular velocity =  $\alpha$ .

Linear velocity =  $\alpha r$ .

Force required to impart this velocity in a unit of time to

$$\text{this particle} = \frac{w}{g} \alpha r.$$

$$\text{Moment of this force about the axis} = \frac{w}{g} \alpha r^2.$$

Hence the moment of the force or forces required to impart to the entire body in a unit of time a rotation about the axis through  $O$ , with an angular velocity  $\alpha$ , is

$$\sum \frac{w}{g} \alpha r^2 = \frac{\alpha}{g} \sum w r^2 = \frac{\alpha I}{g},$$

where  $I$  is used as a symbol to denote the limit of  $\sum w r^2$ , and is called the *Moment of Inertia of the body about the axis through  $O$* .

§ 87. **Angular Momentum.**— This quantity,  $\frac{aI}{g}$ , which expresses the moment of the force or forces required to impart to the body in a unit of time the angular velocity  $a$  about the axis in question is also called the *Angular Momentum of the body when rotating with the angular velocity  $a$  about the given axis.*

§ 88. **Actual Energy of a Rotating Body.**— If it be required to find the actual energy of the body when rotating with the angular velocity  $a$ , we have, for the actual energy of the particle at  $A$ ,

$$\frac{w}{g} \frac{(ar)^2}{2} = \frac{a^2}{2g} wr^2,$$

and for that of the entire body

$$\frac{a^2}{2g} \sum wr^2 = \frac{a^2 I}{2g}.$$

This is the amount of mechanical work which would have to be done to bring the body from a state of rest to the velocity  $a$ , or the total amount of work which the body could do in virtue of its velocity against any resistance tending to stop its rotation.

§ 89. **Moment of Inertia.**— The term “moment of inertia” originated in a wrong conception of the properties of matter. The term has, however, been retained as a very convenient one, although the conceptions under which it originated have long ago vanished. The meaning of the term as at present used, in relation to a solid body, is as follows :—

*The moment of inertia of a body about a given axis is the limit of the sum of the products of the weight of each of the elementary particles that make up the body, by the squares of their distances from the given axis.*

Thus, if  $w_1, w_2, w_3$ , etc., are the weights of the particles which are situated at distances  $r_1, r_2, r_3$ , etc., respectively from

the axis, the moment of inertia of the body about the given axis is

$$I = \text{limit of } \Sigma wr^2.$$

§ 90. **Radius of Gyration.** — The radius of gyration of a body with respect to an axis is the perpendicular distance from the axis to that point at which, if the whole mass of the body were concentrated, the angular momentum, and hence the moment of inertia, of the body, would remain the same as they are in the body itself.

If  $\rho$  is the radius of gyration, the moment of inertia would be, when the mass is concentrated,

$$\rho^2 \Sigma w;$$

hence we must have

$$\rho^2 \Sigma w = \Sigma wr^2 = I,$$

whence

$$\rho^2 = \frac{\Sigma wr^2}{\Sigma w} = \frac{I}{W},$$

where  $W$  = entire weight of the body.

§ 91. **Moment of Inertia of a Plane Surface.** — The term “moment of inertia,” when applied to a plane figure, must, of course, be defined a little differently, as a plane surface has no weight; but, inasmuch as the quantity to which that name is given is necessary for the solution of a great many questions, and also since a knowledge of the manner of determining the moments of inertia of plane figures is very useful in simplifying the determinations of those of solid bodies, we shall now take up those of plane figures.

*The moment of inertia of a plane surface about an axis, either in or not in the plane, is the limit of the sum of the products of the elementary areas into which the surface may be conceived to be divided, by the squares of their distances from the axis in question.*

From this definition it will be evident, that, if the surface be referred to a pair of axes in its own plane, the moment of inertia of the surface about  $OY$  will be

$$I = \iint x^2 dx dy, \quad (1)$$

and the moment of inertia of the surface about  $OX$  will be

$$J = \iint y^2 dx dy. \quad (2)$$

The moment of inertia of the surface about an axis passing through the origin, and perpendicular to the plane  $XOY$ , will be

$$\iint r^2 dx dy, \quad (3)$$

where  $r$  = distance from  $O$  to the point  $(x, y)$ ; hence  $r^2 = x^2 + y^2$ , and the moment of inertia becomes

$$\iint (x^2 + y^2) dx dy = \iint x^2 dx dy + \iint y^2 dx dy = I + J. \quad (4)$$

This is called the "polar moment of inertia." If polar co-ordinates be used, this last becomes

$$\iint \rho^2 (\rho d\rho d\theta) = \iint \rho^3 d\rho d\theta. \quad (5)$$

All these quantities are quantities that will arise in the discussion of stresses, and the letters  $I$  and  $J$  are very commonly used to denote respectively

$$\iint x^2 dx dy \quad \text{and} \quad \iint y^2 dx dy.$$

Another quantity that occurs also, and which will be represented by  $K$ , is

$$\iint xy dx dy; \quad (6)$$

and this is called the moment of deviation.

EXAMPLES.

The following examples will illustrate the mode of finding the moment of inertia:—

1. Find the moment of inertia of the rectangle  $ABCD$  about  $OY$  (Fig. 59).

*Solution.*

$$I = \int_0^b \int_{-\frac{h}{2}}^{\frac{h}{2}} x^2 dx dy = b \int_{-\frac{h}{2}}^{\frac{h}{2}} x^2 dx = \frac{bh^3}{12}.$$

FIG. 59.

2. Find the moment of inertia of the entire circle (radius  $r$ ) about the diameter  $OY$  (Fig. 60).

*Solution.*

FIG. 60.

$$\begin{aligned} I &= \int_{-\sqrt{r^2-x^2}}^{\sqrt{r^2-x^2}} \int_{-\sqrt{r^2-x^2}}^{\sqrt{r^2-x^2}} x^2 dx dy = 2 \int_{-\sqrt{r^2-x^2}}^{\sqrt{r^2-x^2}} x^2 \sqrt{r^2-x^2} dx \\ &= 2 \left\{ -\frac{1}{4}x(r^2-x^2)^{\frac{3}{2}} + \frac{r^2}{4} \int \sqrt{r^2-x^2} dx \right\}_{-\sqrt{r^2-x^2}}^{\sqrt{r^2-x^2}} \\ &= \frac{\pi r^4}{4} = \frac{\pi d^4}{64}. \end{aligned}$$

3. Find the moment of inertia of the circular ring (outside radius  $r$ , inside radius  $r_1$ ) about  $OY$  (Fig. 61).

*Solution.*

$$I = \frac{\pi r^4}{4} - \frac{\pi r_1^4}{4} = \frac{\pi(r^4 - r_1^4)}{4} = \frac{\pi(d^4 - d_1^4)}{64}.$$

FIG. 61.

4. Find the moment of inertia of an ellipse (semi-axes  $a$  and  $b$ ) about the minor axis  $OY$ .

*Solution.*

Equation of ellipse is  $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ .

$$\begin{aligned} \therefore I_y &= \int_{-\frac{b}{a}\sqrt{a^2-x^2}}^{\frac{b}{a}\sqrt{a^2-x^2}} \int_{-a}^a x^2 dx dy \\ &= \frac{2b}{a} \int_{-a}^a x^2 \sqrt{a^2-x^2} dx = \frac{2b}{a} \left( \frac{\pi a^4}{8} \right) = \frac{\pi a^3 b}{4}. \end{aligned}$$

On the other hand,  $I_x = \frac{\pi a b^3}{4}$ .

### § 92. Moments of Inertia of Plane Figures about Parallel Axes.

**PROPOSITION.** — *The moment of inertia of a plane figure about an axis not passing through its centre of gravity is equal to its moment of inertia about a parallel axis passing through its centre of gravity increased by the product obtained by multiplying the area by the square of the distance between the two axes.*

FIG. 62.

**PROOF.** — Let  $ABCD$  (Fig. 62) be the surface; let  $OY$  be the axis not passing through the centre of gravity; let  $P$  be an elementary area  $\Delta x \Delta y$ , whose co-ordinates are  $OP = x$  and  $RP = y$ ; and let  $OO_1 = a =$  a constant = distance between the axes.

Let  $O_1R = x_1 =$  abscissa of  $P$  with reference to the axis passing through the centre of gravity,

$$\begin{aligned} \therefore x &= a + x_1 \\ \therefore x^2 &= x_1^2 + 2ax_1 + a^2 \\ \therefore x^2 \Delta x \Delta y &= x_1^2 \Delta x_1 \Delta y + 2ax_1 \Delta x \Delta y + a^2 \Delta x \Delta y. \end{aligned}$$

Hence, summing, and passing to the limit, we have

$$\iint x^2 dxdy = \iint x_1^2 dxdy + 2a \iint x_1 dxdy + a^2 \iint dxdy; \quad (1)$$

but if we were seeking the abscissa of the centre of gravity when the surface is referred to  $Y, OY$ , and if this abscissa be denoted by  $x_o$ , we should have

$$x_o = \frac{\iint x_1 dxdy}{\iint dxdy};$$

and, since  $x_o = 0$ ,  $\therefore \iint x_1 dxdy = 0$ ; hence, substituting this value in (1), we obtain

$$\iint x^2 dxdy = \iint x_1^2 dxdy + a^2 \iint dxdy. \quad (2)$$

If, now, we call the moment of inertia about  $OY$ ,  $I$ , that about  $O, Y$ ,  $I_1$ , and let the area  $= A = \iint dxdy$ , we shall have

$$I = I_1 + a^2 A. \quad (3)$$

Q. E. D.

§ 93. **Polar Moment of Inertia of Plane Figures.** — *The moment of inertia of a plane figure about an axis perpendicular to the plane is equal to the sum of its moments of inertia about any pair of rectangular axes in its plane passing through the foot of the perpendicular.*

PROOF. — Let  $BCD$  (Fig. 63) be the surface, and  $P$  an elementary area, and let  $OA = x$ ,  $AP = y$ ,  $OP = r$ ; then the moment of inertia of the surface about  $OZ$  will be

$$\iint r^2 dxdy = \iint (x^2 + y^2) dxdy = \iint x^2 dxdy + \iint y^2 dxdy = I + J.$$

Q. E. D.

FIG. 63.

Hence follows, also, that the sum of the moments of inertia of a plane surface relatively to a pair of rectangular axes in its own plane is isotropic; i.e., the same as for any other pair of rectangular axes meeting at the same point, and lying in its plane.

#### EXAMPLES.

1. To find the moment of inertia of the rectangle (Fig. 59) about an axis through its centre perpendicular to the plane of the rectangle.

#### Solution.

$$\text{Moment of inertia about } YY = \frac{bh^3}{12},$$

Moment of inertia about an axis through its

$$\text{centre and perpendicular to } YY = \frac{hb^3}{12};$$

hence

$$\text{Polar moment of inertia} = \frac{bh^3}{12} + \frac{hb^3}{12} = \frac{bh}{12}(h^2 + b^2).$$

2. To find the moment of inertia of a circle about an axis through its centre and perpendicular to its plane (Fig. 60).

#### Solution.

$$\text{Moment of inertia about } OY = \frac{\pi r^4}{4},$$

$$\text{Moment of inertia about } OX = \frac{\pi r^4}{4};$$

hence

$$\text{Polar moment of inertia} = \frac{\pi r^4}{4} + \frac{\pi r^4}{4} = \frac{\pi r^4}{2}.$$

3. To find the moment of inertia of an ellipse about an axis passing through its centre and perpendicular to its plane.

*Solution.*

From example 4, § 91, we have

$$I_x = \frac{\pi ab^3}{4} \quad I_y = \frac{\pi a^3 b}{4}$$

$$\therefore \text{Polar moment of inertia} = \frac{\pi ab}{4}(a^2 + b^2).$$

§ 94. **Moments of Inertia of Plane Figures about Different Axes compared.** — Given the surface  $KLM$  (Fig. 64), suppose we have already determined the quantities

$$I = \iint x^2 dx dy, \quad J = \iint y^2 dx dy, \quad K = \iint xy dx dy,$$

it is required to determine, in terms of them, the quantities

$$I_1 = \iint x_1^2 dx_1 dy_1, \quad J_1 = \iint y_1^2 dx_1 dy_1, \quad K_1 = \iint x_1 y_1 dx_1 dy_1;$$

the angles  $XOY$  and  $X_1OY_1$  being both right angles, and  $YOY_1 = \alpha$ .

We shall have, from the ordinary equations for the transformation of co-ordinates, to be found in any analytic geometry, the equations

$$x_1 = x \cos \alpha + y \sin \alpha,$$

$$y_1 = y \cos \alpha - x \sin \alpha,$$

$$\therefore x_1^2 = x^2 \cos^2 \alpha + y^2 \sin^2 \alpha + 2xy \cos \alpha \sin \alpha,$$

$$y_1^2 = x^2 \sin^2 \alpha + y^2 \cos^2 \alpha - 2xy \cos \alpha \sin \alpha,$$

$$x_1 y_1 = xy(\cos^2 \alpha - \sin^2 \alpha) - (x^2 - y^2) \cos \alpha \sin \alpha.$$

FIG. 64.

Hence

$$\begin{aligned}
 I_1 &= \iint x_1^2 dx_1 dy_1 = \text{limit of } \Sigma x_1^2 \Delta A \\
 &= \cos^2 \alpha \text{ limit of } \Sigma x^2 \Delta A + \sin^2 \alpha \text{ limit of } \Sigma y^2 \Delta A + \\
 &\quad 2 \cos \alpha \sin \alpha \text{ limit of } \Sigma xy \Delta A \\
 &= (\cos^2 \alpha) \iint x^2 dx dy + (\sin^2 \alpha) \iint y^2 dx dy + \\
 &\quad 2(\cos \alpha \sin \alpha) \iint xy dx dy.
 \end{aligned}$$

$$\begin{aligned}
 J_1 &= \iint y_1^2 dx_1 dy_1 = \text{limit of } \Sigma y_1^2 \Delta A \\
 &= (\sin^2 \alpha) \text{ limit of } \Sigma x^2 \Delta A + (\cos^2 \alpha) \text{ limit of } \Sigma y^2 \Delta A - \\
 &\quad 2(\cos \alpha \sin \alpha) \text{ limit of } \Sigma xy \Delta A \\
 &= (\sin^2 \alpha) \iint x^2 dx dy + (\cos^2 \alpha) \iint y^2 dx dy - \\
 &\quad 2(\cos \alpha \sin \alpha) \iint xy dx dy.
 \end{aligned}$$

$$\begin{aligned}
 K_1 &= \iint x_1 y_1 dx_1 dy_1 = \text{limit of } \Sigma x_1 y_1 \Delta A \\
 &= (\cos^2 \alpha - \sin^2 \alpha) \text{ limit of } \Sigma xy \Delta A - (\cos \alpha \sin \alpha) \{ \text{limit of } \\
 &\quad \Sigma x^2 \Delta A - \text{limit of } \Sigma y^2 \Delta A \} \\
 &= (\cos^2 \alpha - \sin^2 \alpha) \iint xy dx dy - (\cos \alpha \sin \alpha) \{ \iint x^2 dx dy - \\
 &\quad \iint y^2 dx dy \}.
 \end{aligned}$$

Or, introducing the letters  $I$ ,  $J$ , and  $K$ , we have

$$I_1 = I \cos^2 \alpha + J \sin^2 \alpha + 2K \cos \alpha \sin \alpha, \quad (1)$$

$$J_1 = I \sin^2 \alpha + J \cos^2 \alpha - 2K \cos \alpha \sin \alpha, \quad (2)$$

$$K_1 = - (J - I) \cos \alpha \sin \alpha + K (\cos^2 \alpha - \sin^2 \alpha). \quad (3)$$

The equations (1), (2), and (3) furnish the solution of the problem.

§ 95. **Principal Moments of Inertia in a Plane.** — *In every plane figure, a given point being assumed as origin, there is at least one pair of rectangular axes, about one of which the moment of inertia is a maximum, and a minimum about the other; these moments of inertia being called principal moments of inertia, and the axes about which they are taken being called principal axes of inertia.*

PROOF. — In order that  $I_{\alpha}$ , equation (1), § 94, may be a maximum or a minimum, we must have, as will be seen by differentiating its value, and putting the first differential co-efficient equal to zero,

$$-2I \cos \alpha \sin \alpha + 2J \cos \alpha \sin \alpha + 2K(\cos^2 \alpha - \sin^2 \alpha) = 0$$

$$\therefore K(\cos^2 \alpha - \sin^2 \alpha) - (I - J) \cos \alpha \sin \alpha = 0 \quad (1)$$

$$\therefore \frac{\cos \alpha \sin \alpha}{\cos^2 \alpha - \sin^2 \alpha} = -\frac{K}{I - J} \quad \therefore \tan 2\alpha = -\frac{2K}{I - J} \quad (2)$$

Hence, for the value of  $\alpha$  given by (2), we have  $I_{\alpha}$  a maximum or a minimum; and as there are two values of  $2\alpha$  corresponding to the same value of  $\tan 2\alpha$ , and as these two values differ by  $180^\circ$ , the values of  $\alpha$  will differ by  $90^\circ$ , one corresponding to a maximum and the other to a minimum.

Moreover, when the value of  $\alpha$  is so chosen, we have

$$K_{\alpha} = 0,$$

as is proved by equation (1). Indeed, we might say that the condition for determining the principal axes of inertia is

$$K_{\alpha} = 0.$$

§ 96. **Axes of Symmetry of Plane Figures.** — An axis which divides the figure symmetrically is always a principal axis.

PROOF. — Let us assume that the  $y$  axis divides the surface symmetrically; then we shall have, with reference to this axis,

$$K = \int_{-x}^x \int xy dy dx = \left\{ \int_{-x}^x \frac{x^2}{2} y dy \right\}_{-x}^x = 0.$$

And, since  $K$  is zero, the axis of  $y$  is one principal axis, and of course the axis of  $x$  is the other. The same method of reasoning would show  $K = 0$  if the  $x$  axis were the axis of symmetry.

Hence, whenever a plane figure has an axis of symmetry, this axis is one of the principal axes, and the other is at right angles to it. Thus, for a rectangle, when the axis is to pass through its centre of gravity, the principal axes are parallel to the sides respectively, the moment of inertia being greatest about the shortest axis, and least about the longest. Thus in an ellipse the minor axis is the axis of maximum, and the major that of minimum, moment of inertia, etc. On the other hand, in a circle, or in a square, since the maximum and minimum are equal, it follows that the moments of inertia about all axes passing through the centre are the same.

§ 97. **Conditions for Equal Values of Moment of Inertia.**—When the moments of inertia of a plane figure about three different axes passing through the same point are the same, the moments of inertia about all axes passing through this point are the same.

PROOF.—Let  $I$  be the moment of inertia about  $OY$ ,  $I_1$  about  $OY_1$ ,  $I_2$  about  $OY_2$ , and let

$$YOY_1 = \alpha, \quad YOY_2 = \beta,$$

and let

$$I_1 = I_2 = I.$$

Then, from equation (1), § 94, we have

$$I = I \cos^2 \alpha + J \sin^2 \alpha + 2K \cos \alpha \sin \alpha,$$

$$I = I \cos^2 \beta + J \sin^2 \beta + 2K \cos \beta \sin \beta.$$

Hence

$$(I - J) \sin^2 \alpha = 2K \cos \alpha \sin \alpha, \quad (1)$$

$$(I - J) \sin^2 \beta = 2K \cos \beta \sin \beta. \quad (2)$$

Hence

$$(I - J) \tan \alpha = 2K, \quad (3)$$

$$(I - J) \tan \beta = 2K. \quad (4)$$

And, since  $\tan \alpha$  is not equal to  $\tan \beta$ , we must have

$$I - J = 0 \quad \text{and} \quad K = 0.$$

Hence, since  $K = 0$  and  $I = J$ , we shall have, from equa-

tion (1), § 94, for the moment of inertia  $I'$  about an axis, making any angle  $\theta$  with  $OY$ ,

$$I' = I \cos^2 \theta + I \sin^2 \theta + 0 = I. \quad (5)$$

Hence all the moments of inertia are equal.

§ 98. **Components of Moments of Inertia of Solid Bodies.** — Refer the body to three rectangular axes,  $OX$ ,  $OY$ , and  $OZ$ ; and let  $I_x$ ,  $I_y$ , and  $I_z$  represent its moment of inertia about each axis respectively. Then, if  $r$  denote the distance of any particle from  $OZ$ , we shall have

$$I_z = \text{limit of } \Sigma wr^2;$$

but

$$r^2 = x^2 + y^2$$

$$\therefore I_z = \text{limit of } \Sigma w(x^2 + y^2) = \text{limit of } \Sigma wx^2 + \text{limit of } \Sigma wy^2. \quad (1)$$

In the same way we have

$$I_x = \text{limit of } \Sigma wy^2 + \text{limit of } \Sigma wz^2, \quad (2)$$

$$I_y = \text{limit of } \Sigma wx^2 + \text{limit of } \Sigma wz^2. \quad (3)$$

§ 99. **Moments of Inertia of Solids around Parallel Axes.** — The moment of inertia of a solid body about an axis not passing through its centre of gravity is equal to its moment of inertia about a parallel axis passing through the centre of gravity, increased by the product of the entire weight of the body by the square of the distance between the two axes.

PROOF. — Refer the body to a system of three rectangular axes,  $OX$ ,  $OY$ , and  $OZ$ , of which  $OZ$  is the one about which the moment of inertia is taken. Let the co-ordinates of the centre of gravity of the body with reference to these axes be  $(x_0, y_0, z_0)$ . Through the centre of gravity of the body draw a system of rectangular axes, parallel respectively to  $OX$ ,  $OY$ , and  $OZ$ . Then we shall have for the co-ordinates of any point

$$x = x_0 + x_1,$$

$$y = y_0 + y_1,$$

$$z = z_0 + z_1.$$

Hence

$$\begin{aligned}
 I_s &= \text{limit of } \Sigma w(x^2 + y^2) = \text{limit of } \Sigma wx^2 + \text{limit of } \Sigma wy^2 \\
 &= \text{limit of } \Sigma w(x_0 + x_1)^2 + \text{limit of } \Sigma w(y_0 + y_1)^2 \\
 &= x_0^2 \text{ limit of } \Sigma w + y_0^2 \text{ limit of } \Sigma w + 2x_0 \text{ limit of } \Sigma wx_1 \\
 &\quad + 2y_0 \text{ limit of } \Sigma wy_1 + \text{limit of } \Sigma wx_1^2 + \text{limit of } \Sigma wy_1^2 \\
 &= (x_0^2 + y_0^2)W + 2x_0 \text{ limit of } \Sigma wx_1 + 2y_0 \text{ limit of } \Sigma wy_1 \\
 &\quad + \text{limit of } \Sigma wx_1^2 \\
 &= r_0^2 W + I_s' + 2x_0 \text{ limit of } \Sigma wx_1 + 2y_0 \text{ limit of } \Sigma wy_1.
 \end{aligned}$$

But, since  $O$  is the centre of gravity,

$$\therefore \Sigma wx_1 = 0 \quad \text{and} \quad \Sigma wy_1 = 0.$$

Hence

$$I_s = I_s' + Wr_0^2,$$

which proves the proposition.

### § 100. Examples of Moments of Inertia.

1. To find the moment of inertia of a sphere whose radius is  $r$  and weight per unit of volume  $w$ , about the axis  $OZ$  drawn through its centre.

*Solution.*

Divide the sphere into thin slices (Fig. 65) by planes drawn perpendicular to  $OZ$ . Let the distance of the slice shown in the figure, above  $O$  be  $z$ , and its thickness  $dz$ : then will its radius be  $\sqrt{r^2 - z^2}$ ; and we can readily see, from example 2, § 93, that its moment of inertia about  $OZ$  will be

FIG. 65.

$$\frac{w\pi(r^2 - z^2)^2}{2} dz.$$

Hence the moment of inertia of the entire sphere about  $OZ$  will be

$$I_s = w \frac{\pi}{2} \int_{-r}^r (r^2 - z^2)^2 dz,$$

which easily reduces to

$$I_z = \frac{8}{15} w \pi r^5.$$

2. To find the moment of inertia of an ellipsoid (semi-axes  $a, b, c$ ) about  $OZ$  (Fig. 66).

SOLUTION.—The equation of the ellipsoid is

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1.$$

Divide it into thin slices perpendicular to  $OZ$ , and let the slice shown in the figure be at a distance  $z$  from  $O$ . Then will this slice be elliptical, and its semi-axes will be

FIG. 66.

$$\frac{a}{c} \sqrt{c^2 - z^2} \quad \text{and} \quad \frac{b}{c} \sqrt{c^2 - z^2};$$

and from example 3, § 93, we readily obtain, for its moment of inertia about  $OZ$ ,

$$\begin{aligned} \frac{w\pi}{4} \left[ \frac{ab}{c^2} (c^2 - z^2) \right] \left\{ \frac{a^2}{c^2} (c^2 - z^2) + \frac{b^2}{c^2} (c^2 - z^2) \right\} dz \\ = \frac{w\pi ab(a^2 + b^2)}{4c^4} (c^2 - z^2)^2 dz. \end{aligned}$$

Hence, for the moment of inertia of the ellipsoid about  $OZ$ , we have

$$I_z = \frac{w\pi ab(a^2 + b^2)}{4c^4} \int_{-c}^c (c^2 - z^2)^2 dz = \frac{4}{15} w\pi abc(a^2 + b^2).$$

3. Find the moment of inertia of a right circular cylinder, length  $a$ , radius  $r$ , about its axis.

$$\text{Ans.} \quad \frac{w\pi r^4 a}{2}.$$

4. Find the moment of inertia of the same about an axis perpendicular to, and bisecting its axis.

$$\text{Ans. } \frac{w\pi ar^3}{4} \left( r^2 + \frac{a^2}{3} \right).$$

5. Find the moment of inertia of an elliptic right cylinder, length  $2c$ , transverse semi-axes  $a$  and  $b$ , about its longitudinal axis.

$$\text{Ans. } \frac{w\pi abc}{2} (a^2 + b^2).$$

6. Find the moment of inertia of the same about its transverse axis  $2b$ .

$$\text{Ans. } 2w\pi abc \left( \frac{a^2}{4} + \frac{c^2}{3} \right).$$

7. Find the moment of inertia of a rectangular prism, sides  $2a$ ,  $2b$ ,  $2c$ , about central axis  $2c$ .

$$\text{Ans. } \frac{8}{3} wabc (a^2 + b^2).$$

§ 101. Centre of Percussion. — Suppose we have a body revolving about an axis perpendicular to the plane of the paper, and passing through  $O$ , with an angular velocity  $\omega$ . If, with  $O$  as a centre and a radius  $OA = r$ , we describe an arc  $CB$  (Fig. 67), all particles situated in this arc have a linear velocity  $\omega r$ . The measure of the force which would impart

FIG. 67.

this velocity to the particle in a unit of time is

$$\frac{w}{g} \omega r,$$

and the moment of this force about the axis is

$$\frac{w}{g} \omega r^2;$$

hence the total angular momentum, or the total moment of the

forces which would impart to the body in a unit of time the angular velocity  $\alpha$ , is, as has been shown already,

$$\frac{\alpha I}{g} = \frac{\alpha}{g} \Sigma w r^2.$$

The sum of the forces acting on the body is, on the other hand,

$$\frac{\alpha}{g} \Sigma w r.$$

Hence the perpendicular distance from  $O$  to the line of direction of the resultant force is

$$l = \frac{\frac{\alpha}{g} I}{\frac{\alpha}{g} \Sigma w r} = \frac{I}{\Sigma w r}; \quad (1)$$

and if a line be drawn from  $O$  in the plane of the paper, perpendicular to the direction of the resultant, and the length  $l$ , as deduced above, laid off, the resultant force may be conceived to have its point of application at this point, and this point of application of the resultant of the forces which produce the rotation is called the *Centre of Percussion*.

If  $\rho$  = radius of gyration about the axis through  $O$ , and if  $r_o$  = distance from  $O$  to the centre of gravity, we have

$$r_o \Sigma w = \Sigma w r.$$

Hence

$$l = \frac{\Sigma w r^2}{\Sigma w r} = \frac{I}{r_o \Sigma w} = \frac{1}{r_o} \left( \frac{I}{W} \right) = \frac{\rho^2}{r_o} \therefore \rho^2 = r_o l;$$

or, in words, —

*The radius of gyration is a mean proportional between the distance  $l$ , and the distance  $r_o$  between the axis of oscillation and the centre of gravity.*

*The centre of percussion with respect to a given centre of oscillation  $O$  has been defined as the point of application of the*

*resultant of the forces which cause the body to rotate around the point O.*

Another definition often given is, that it is *the point at which, if a force be applied, there will be no shock on the axis of oscillation*; and these two definitions are equivalent to each other.

Let the particles of the body under consideration be conceived, for the sake of simplicity, to be distributed along a single line  $AB$ , and suppose a force  $F$  applied at  $D$  (Fig. 68). Conceive two equal and opposite forces, each equal to  $F$ , applied at  $C$ , the centre of gravity of the body.

FIG. 68.

Then these three forces are equivalent to a single force  $F$  applied at the centre of gravity  $C$ , which produces translation of the whole body; and, secondly, a couple whose moment is  $F(CD)$ , whose effect is to produce rotation around an axis passing through the centre of gravity  $C$ . Under this condition of things it is evident that the centre of gravity  $C$  will have imparted to it in a unit of time a forward velocity equal to  $\frac{F}{M}$ , where  $M$  is the entire mass of the

body; the point  $D$  will have imparted to it a greater forward velocity; while those points on the upper side of  $C$  will have imparted to them a less and less velocity as they recede from  $C$ , until, if the rod is sufficiently long, the particle at  $A$  will acquire a backward velocity.

Hence there must be some point which for the instant in question is at rest; i.e., where the velocity due to rotation is just equal and opposite to that due to the translation, or, about which, for the instant, the body is rotating: and if this point were fixed by a pivot, there would be no stress on the pivot caused by the force applied at  $D$ .

An axis through this point is called the *Instantaneous Axis*.

§ 102. **Interchangeability of the Centre of Percussion and Centre of Oscillation.** — If we take our centre of percussion  $D$  as axis of oscillation, then will  $O$  be the new centre of percussion.

PROOF. — We have seen (§ 101) that

$$l = \frac{\rho^2}{r_o},$$

where  $l = OD$ ,  $r_o = OC$ , and  $\rho$  = radius of gyration about an axis through  $O$  perpendicular to the plane of the paper.

Moreover, if  $\rho_o$  represent the radius of gyration about an axis through  $C$  perpendicular to the plane of the paper, we shall have

$$\begin{aligned}\rho^2 &= \rho_o^2 + r_o^2 \\ \therefore l &= \frac{\rho_o^2}{r_o} + r_o \\ \therefore l - r_o &= \frac{\rho_o^2}{r_o} = CD.\end{aligned}$$

Now if  $D$  is taken as axis of oscillation, we shall have for the distance  $l_1$  to the corresponding centre of percussion,

$$l_1 = \frac{\rho_1^2}{CD} = \frac{\rho_1^2}{l - r_o},$$

where  $\rho_1$  = radius of gyration about the axis of oscillation through  $D$ .

$$\therefore l_1 = \frac{\rho_1^2}{CD} = \frac{\rho_o^2 + CD^2}{CD} = \frac{\rho_o^2}{CD} + CD = r_o + (l - r_o) = l.$$

Hence the new centre of percussion is at  $O$ . Q. E. D.

§ 103. **Impact or Collision.** — Impact or collision is a pressure of inappreciably short duration between two bodies.

The direction of the force of impact is along the straight line drawn normal to the surfaces of the colliding bodies at their point of contact, and we may call this line the line of impact.

The action that occurs in the case of collision may be described as follows: at first the bodies undergo compression; the mutual pressure between them constantly increasing, until, when it has reached its maximum, the elasticity of the materials begins to overpower the compressive force, and restore the bodies wholly or partially to their original shape and dimensions.

Central impact occurs when the line joining the centres of gravity of the bodies coincides with the line of impact.

Eccentric impact occurs when these lines do not coincide.

Direct impact occurs when the line along which the relative motion of the bodies takes place, coincides with the line of impact.

Oblique impact occurs when these lines do not coincide.

#### CENTRAL IMPACT.

§ 104. **Equality of Action and Re-action.**—One fundamental principle that holds in all cases of central impact is the equality of action and re-action; in other words, we must have, that, at every instant of the time during which the impact is taking place, the pressure that one body exerts upon the other is equal and opposite to that exerted by the second upon the first.

The direct consequence of this principle is, that the algebraic sum of the momenta of the two bodies before impact remains unaltered by the impact, and hence that this sum is just the same at every instant of, and after, the impact.

If we let

$m_1, m_2$ , be the respective masses,

$c_1, c_2$ , their respective velocities before impact,

$v_1, v_2$ , their respective velocities after impact,

$v', v''$ , their respective velocities at any given instant during the time while impact is taking place,

then we must have the following two equations true; viz., —

$$m_1 v_1 + m_2 v_2 = m_1 c_1 + m_2 c_2, \quad (1)$$

$$m_1 v' + m_2 v'' = m_1 c_1 + m_2 c_2. \quad (2)$$

§ 105. **Velocity at Time of Greatest Compression.** — At the instant when the compression is greatest — i.e., at the instant when the elasticity of the bodies begins to overcome the deformation due to the impact, and to tend to restore them to their original forms — the values of  $v'$  and  $v''$  must be equal to each other; in other words, the colliding bodies must be moving with a common velocity

$$v = v' = v''. \quad (1)$$

To determine this velocity, we have, from equation (2), § 104, combined with (1),

$$v = \frac{m_1 c_1 + m_2 c_2}{m_1 + m_2}. \quad (2)$$

§ 106. **Co-efficient of Restitution.** — In order to determine the values  $v_1$ ,  $v_2$ , of the velocities after impact, we need two equations, and hence two conditions. One of them is furnished by equation (1), § 104. The second depends upon the nature of the material of the colliding bodies, and we may distinguish three cases: —

1°. *Inelastic Impact.* — In this case the velocity lost up to the time of greatest compression is not regained at all, and the velocity after impact is the common velocity  $v$  at the instant of greatest compression. In this case the whole of the work used up in compressing the bodies is lost, as none of it is restored by the elasticity of the material.

2°. *Elastic Impact.* — In this case the velocity regained after the greatest compression, is equal and opposite to that lost up to the time of greatest compression; therefore

$$v - v_1 = c_1 - v. \quad (1) \qquad v_2 - v = v - c_2. \quad (2)$$

We may also define this case as that in which the work lost in compressing the bodies is entirely restored by the elasticity of the material, so that

$$\frac{m_1 v_1^2}{2} + \frac{m_2 v_2^2}{2} = \frac{m_1 c_1^2}{2} + \frac{m_2 c_2^2}{2}. \quad (3)$$

Either condition will lead to the same result.

3°. *Imperfectly Elastic Impact.* — In this case a part only of the velocity lost up to the time of greatest compression is regained after that time.

If, when the two bodies are of the same material, we call  $e$  the co-efficient of restitution, then we shall so define it that

$$\frac{v - v_1}{c_1 - v} = \frac{v_2 - v}{v - c_2} = e;$$

or, in words, the co-efficient of restitution is the ratio of the velocity regained after compression to that lost previous to that time.

In this case only a part of the work done in producing the compression is regained, hence there is loss of energy. Its amount will be determined later.

Strictly speaking, all bodies belong to the third class; the value of  $e$  being always a proper fraction, and never reaching unity, the value corresponding to perfect elasticity; nor zero, the value corresponding to entire lack of elasticity.

§ 107. *Inelastic Impact.* — In this case the velocity after impact is the common velocity at the time of greatest compression; hence

$$v = v_1 = v_2 \quad (1)$$

$$\therefore v = \frac{m_1 c_1 + m_2 c_2}{m_1 + m_2}. \quad (2)$$

And for the loss of energy due to impact we have

$$\frac{m_1 c_1^2}{2} + \frac{m_2 c_2^2}{2} - (m_1 + m_2) \frac{v^2}{2},$$

which, on substituting the value of  $v$ , reduces to

$$\frac{m_1 m_2}{2(m_1 + m_2)} (c_1 - c_2)^2. \quad (3)$$

§ 108. **Elastic Impact.** — In this case we have, of course, the condition, equation (1), § 104,

$$m_1 v_1 + m_2 v_2 = m_1 c_1 + m_2 c_2,$$

and, for second equation, we may use equation (3), § 106; viz.,

$$\frac{m_1 v_1^2}{2} + \frac{m_2 v_2^2}{2} = \frac{m_1 c_1^2}{2} + \frac{m_2 c_2^2}{2}.$$

Combining these two equations, we shall obtain

$$v_1 = c_1 - \frac{2m_2(c_1 - c_2)}{m_1 + m_2}, \quad (1)$$

$$v_2 = c_2 + \frac{2m_1(c_1 - c_2)}{m_1 + m_2}. \quad (2)$$

We can obtain the same result without having to solve an equation of the second degree, by using instead the equations (1) and (2) of § 106, together with (1) of § 104; i.e., —

$$m_1 v_1 + m_2 v_2 = m_1 c_1 + m_2 c_2;$$

$$v - v_1 = c_1 - v,$$

or

$$v_2 - v = v - c_2,$$

and (§ 105)

$$v = \frac{m_1 c_1 + m_2 c_2}{m_1 + m_2}.$$

As the result of combining these equations, and eliminating  $v$ , we should obtain equations (1) and (2), as above, for the values of  $v_1$  and  $v_2$ . In this case the energy lost by the collision is zero.

§ 109. Special Cases of Inelastic Impact. — (a) Let the mass  $m_2$  be at rest. Then  $c_2 = 0$ .

$$\therefore v = \frac{m_1 c_1}{m_1 + m_2} \quad (1)$$

$$\therefore \text{Loss of energy} = \frac{m_1 m_2}{m_1 + m_2} \frac{c_1^2}{2}. \quad (2)$$

(b) Let  $m_2$  be at rest, and let  $m_2 = \infty$ ; i.e., let the mass  $m_1$  strike against another which is at rest, and whose mass is infinite. We have

$$m_2 = \infty, \quad c_2 = 0,$$

$$\therefore v = \frac{m_1 c_1}{m_1 + m_2} = 0, \quad (3)$$

$$\text{Loss of energy} = \frac{m_1}{\frac{m_1}{m_2} + 1} \frac{c_1^2}{2} = \frac{m_1 c_1^2}{2}, \quad (4)$$

or the moving body is reduced to rest by the collision, and all its energy is expended in compression.

(c) Let  $m_1 c_1 = -m_2 c_2$ ; i.e., let the two bodies move towards each other with equal momenta:

$$\therefore v = \frac{m_1 c_1 + m_2 c_2}{m_1 + m_2} = 0, \quad (5)$$

$$\text{and the loss of energy} = \frac{m_1 c_1^2}{2} + \frac{m_2 c_2^2}{2}, \quad (6)$$

the entire energy being lost.

§ 110. Special Cases of Elastic Impact. — (a) Let the mass  $m_2$  be at rest. Then  $c_2 = 0$ ,

$$v_1 = c_1 - \frac{2m_2 c_1}{m_1 + m_2} \quad (1)$$

$$\therefore v_2 = \frac{2m_1 c_1}{m_1 + m_2}. \quad (2)$$

(b) Let  $m_2$  be at rest, and let  $m_2 = \infty$ . Then we have  $c_2 = 0$ ,

$$\therefore v_1 = c_1 - \frac{2c_1}{\frac{m_1}{m_2} + 1} = c_1 - 2c_1 = -c_1, \quad (3)$$

$$v_2 = 0. \quad (4)$$

Hence the moving body retraces its path in the opposite direction with the same velocity.

(c) Let  $m_1 c_1 = -m_2 c_2$ . Then our equations of condition become

$$m_1 v_1 + m_2 v_2 = 0,$$

$$\frac{m_1 v_1^2}{2} + \frac{m_2 v_2^2}{2} = \frac{m_1 c_1^2}{2} + \frac{m_2 c_2^2}{2};$$

and from these we readily obtain

$$v_1 = -c_1,$$

$$v_2 = -c_2;$$

i.e., both bodies return on their path with the same velocity with which they approached each other.

### § 111. Examples of Elastic and of Inelastic Impact.

1. With what velocity must a body weighing 8 pounds strike one weighing 25 pounds in order to communicate to it a velocity of 2 feet per second, (a) when the bodies are perfectly elastic, (b) when wholly inelastic.

2. Suppose sixteen impacts per minute take place between two bodies whose weights are respectively 1000 and 1200 pounds, their initial velocities being 5 and 2 feet per second respectively: find the loss of energy, the bodies being inelastic.

§ 112. Imperfect Elasticity. — In this case we have the relations (see § 106)

$$\frac{v - v_1}{c_1 - v} = \frac{v_2 - v}{v - c_2} = e,$$

where

$$v = \frac{m_1 c_1 + m_2 c_2}{m_1 + m_2};$$

and we have also

$$m_1 v_1 + m_2 v_2 = m_1 c_1 + m_2 c_2.$$

Determining from them the values of  $v_1$  and  $v_2$ , we obtain

$$v_1 = v(1 + e) - ec_1, \quad (1)$$

$$v_2 = v(1 + e) - ec_2, \quad (2)$$

or, by substituting for  $v$  its value,

$$v_1 = \frac{m_1 c_1 + m_2 c_2}{m_1 + m_2} (1 + e) - ec_1, \quad (3)$$

$$v_2 = \frac{m_1 c_1 + m_2 c_2}{m_1 + m_2} (1 + e) - ec_2. \quad (4)$$

These may otherwise be put in the form

$$v_1 = c_1 - (1 + e) \frac{m_2}{m_1 + m_2} (c_1 - c_2), \quad (5)$$

$$v_2 = c_2 + (1 + e) \frac{m_1}{m_1 + m_2} (c_1 - c_2). \quad (6)$$

Moreover, we have for the loss of energy due to impact

$$E = \frac{m_1}{2} (c_1^2 - v_1^2) + \frac{m_2}{2} (c_2^2 - v_2^2)$$

or

$$E = \frac{1}{2} \{ m_1 (c_1 - v_1) (c_1 + v_1) + m_2 (c_2 - v_2) (c_2 + v_2) \};$$

but, from (5) and (6) respectively,

$$c_1 - v_1 = \frac{(1 + e) m_2 (c_1 - c_2)}{m_1 + m_2}$$

$$c_2 - v_2 = - \frac{(1 + e) m_1 (c_1 - c_2)}{m_1 + m_2}$$

$$\therefore E = \frac{(1 + e)(c_1 - c_2)}{2(m_1 + m_2)} \{m_1 m_2 (c_1 + v_1) - m_1 m_2 (c_2 + v_2)\}$$

$$\therefore E = \frac{m_1 m_2}{2(m_1 + m_2)} (c_1 - c_2)(1 + e)(c_1 - c_2 + v_1 - v_2).$$

But, from (1) and (2),

$$v_1 - v_2 = -e(c_1 - c_2)$$

$$\therefore E = \frac{m_1 m_2}{2(m_1 + m_2)} (c_1 - c_2)(1 + e)(c_1 - c_2)(1 - e)$$

or

$$E = (1 - e^2) \frac{m_1 m_2}{2(m_1 + m_2)} (c_1 - c_2)^2. \quad (7)$$

When  $e = 1$ , or the elasticity is perfect, this loss of energy becomes zero.

When  $e = 0$ , or the bodies are totally inelastic, then the loss of energy becomes

$$\frac{m_1 m_2}{2(m_1 + m_2)} (c_1 - c_2)^2, \quad (8)$$

as has been already shown in § 107.

An interesting fact in this connection is, that since (8) is the work expended in producing compression, and (7) is the work lost in all, therefore the work restored by the elasticity of the body is

$$e^2 \left\{ \frac{m_1 m_2}{2(m_1 + m_2)} (c_1 - c_2)^2 \right\}; \quad (9)$$

so that  $e^2$ , or the square of the co-efficient of restitution, is the ratio of the work restored by the elasticity of the bodies, to the work expended in compressing the bodies up to the time of greatest compression.

§ 113. Special Cases. — (a) Let  $m_2$  be at rest, therefore  $c_2 = 0$ . Then we shall have

$$v_1 = c_1 \left\{ 1 - \frac{m_2(1 + e)}{m_1 + m_2} \right\} = c_1 \frac{m_1 - e m_2}{m_1 + m_2}, \quad (1)$$

$$v_2 = (1 + e)c_1 \frac{m_1}{m_1 + m_2}, \quad (2)$$

and for loss of energy

$$E = (1 - e^2) \frac{m_1 m_2}{2(m_1 + m_2)} c_1^2. \quad (3)$$

(b) When  $m_2 = \infty$ , and  $c_2 = 0$ , we have

$$v_1 = -e c_1, \quad (4)$$

$$v_2 = 0,$$

$$E = (1 - e^2) \frac{m_1 c_1^2}{2}. \quad (5)$$

(c) When  $m_1 c_1 = -m_2 c_2$ , then

$$v_1 = -e c_1,$$

$$v_2 = -e c_2,$$

$$\begin{aligned} E &= \frac{(1 - e^2) m_1 c_1 (c_1 - c_2)}{2} = \frac{(1 - e^2) m_2 c_2 (c_2 - c_1)}{2} \\ &= (1 - e^2) \frac{m_1 (m_1 + m_2)}{2 m_2} c_1^2. \end{aligned} \quad (6)$$

§ 114. Values of  $e$  as Determined by Experiment. — Since we have

$$e = \frac{v - v_1}{c_1 - v},$$

we shall have, when

$$m_2 = \infty \quad \text{and} \quad c_2 = 0,$$

$$v = \frac{m_1 c_1 + m_2 c_2}{m_1 + m_2} = 0.$$

Hence

$$e = -\frac{v_1}{c_1}.$$

Now, if we let a round ball fall vertically upon a horizontal slab from the height  $H$ , we shall have for the velocity of approach

$$c_1 = \sqrt{2gH};$$

and if we measure the height  $h$  to which it rises on its rebound, we shall have

$$-v_1 = \sqrt{2gh}.$$

Hence

$$e = -\frac{v_1}{c_1} = \sqrt{\frac{h}{H}}$$

In this way the value of  $e$  can be determined experimentally for different substances.

Newton found for values of  $e$ : for glass,  $\frac{1}{2}$ ; for steel,  $\frac{1}{3}$ ; and Coriolis gives for ivory from 0.5 to 0.6.

On the other hand, if we desired to adopt as our constant the ratio of the work restored, to the work spent in compression, we should have for our constant  $e^2$ , and hence the squares of the preceding numbers.

#### EXAMPLES.

1. If two trains of cars, weighing 120000 and 160000 lbs., come into collision when they are moving in opposite directions with velocities 20 and 15 feet per second respectively, what is the loss of mechanical effect expended in destroying the locomotives and cars?

2. Two perfectly inelastic balls approach each other with equal velocities, and are reduced to rest by the collision; what must be the ratio of their weights?

3. Two steel balls, weighing 10 lbs. each, are moving with velocities 5 and 10 feet per second respectively, and in the same direction: find their velocities after impact, the fastest ball being in the rear, and overtaking the other; also the loss of mechanical effect due to the impact, assuming  $e = 0.55$ .

### § 115. Oblique Impact.

Let  $m_1, m_2$ , be the masses of the colliding bodies;

$c_1, c_2$ , their respective velocities before impact;

$\alpha_1, \alpha_2$ , the angles made by  $c_1, c_2$ , with the line of centres;

$v_1, v_2$ , the components of the velocities after impact;

$c_1 \cos \alpha_1, c_2 \cos \alpha_2$ , the components of  $c_1, c_2$ , along the line of centres;

$c_1 \sin \alpha_1, c_2 \sin \alpha_2$ , the components of  $c_1, c_2$ , at right angles to the line of centres;

$v$  the common component of the velocity at the instant of greatest compression along line of centres;

$v', v''$ , actual velocities after impact;

$\alpha', \alpha''$ , angles they make with line of centres;

$v'_c, v''_c$ , actual velocities when compression is greatest;

$\alpha'_c, \alpha''_c$ , angles they make with line of centres.

Then we shall have, by proceeding in the same way as was done in § 112,

$$v_1 = c_1 \cos \alpha_1 - (1 + e) \frac{m_2}{m_1 + m_2} (c_1 \cos \alpha_1 - c_2 \cos \alpha_2), \quad (1)$$

$$v_2 = c_2 \cos \alpha_2 + (1 + e) \frac{m_1}{m_1 + m_2} (c_1 \cos \alpha_1 - c_2 \cos \alpha_2), \quad (2)$$

$$v' = \sqrt{v_1^2 + c_1^2 \sin^2 a_1}, \quad (3)$$

$$v'' = \sqrt{v_2^2 + c_2^2 \sin^2 a_2}, \quad (4)$$

$$\cos a' = \frac{v_1}{v'}, \quad (5)$$

$$\cos a'' = \frac{v_2}{v''}, \quad (6)$$

$$v = \frac{m_1 c_1 \cos a_1 + m_2 c_2 \cos a_2}{m_1 + m_2}, \quad (7)$$

$$v_c' = \sqrt{v^2 + c_1^2 \sin^2 a_1}, \quad (8)$$

$$v_c'' = \sqrt{v^2 + c_2^2 \sin^2 a_2}, \quad (9)$$

$$\cos a_c' = \frac{v}{v_c'}, \quad (10)$$

$$\cos a_c'' = \frac{v}{v_c''}. \quad (11)$$

And for the energy lost in impact, we have

$$E = (1 - e^2) \frac{m_1 m_2}{2(m_1 + m_2)} (c_1 \cos a_1 - c_2 \cos a_2)^2. \quad (12)$$

When the bodies are perfectly elastic,

$$e = 1,$$

and equations (1), (2), and (12) become respectively

$$v_1 = c_1 \cos a_1 - \frac{2m_2}{m_1 + m_2} (c_1 \cos a_1 - c_2 \cos a_2),$$

$$v_2 = c_2 \cos a_2 + \frac{2m_1}{m_1 + m_2} (c_1 \cos a_1 - c_2 \cos a_2),$$

$$E = 0.$$

The rest remain the same in form.

When the bodies are totally inelastic,

$$e = 0,$$

and equations (1), (2), and (12) become respectively

$$v_1 = c_1 \cos \alpha_1 - \frac{m_2}{m_1 + m_2} (c_1 \cos \alpha_1 - c_2 \cos \alpha_2),$$

$$v_2 = c_2 \cos \alpha_2 + \frac{m_1}{m_1 + m_2} (c_1 \cos \alpha_1 - c_2 \cos \alpha_2),$$

$$E = \frac{m_1 m_2}{2(m_1 + m_2)} (c_1 \cos \alpha_1 - c_2 \cos \alpha_2)^2.$$

The rest remain the same in form.

§ 116. **Impact of Revolving Bodies.** — Let the bodies *A* and *B* revolve about parallel axes, and impinge upon each other.

Draw a common normal at the point of contact. This common normal will be the line of impact.

Let  $\epsilon_1$  = angular velocity of *A* before impact,

$\epsilon_2$  = angular velocity of *B* before impact,

$\omega_1$  = angular velocity of *A* after impact,

$\omega_2$  = angular velocity of *B* after impact,

$a_1$  = perpendicular from axis of *A* on line of impact,

$a_2$  = perpendicular from axis of *B* on line of impact,

$I_1$  = moment of inertia of *A* about its axis,

$I_2$  = moment of inertia of *B* about its axis.

Then we shall have

$$a_1 \epsilon_1 = c_1 \quad = \text{linear velocity of } A \text{ at point of contact before impact ;}$$

$$a_2 \epsilon_2 = c_2 \quad = \text{linear velocity of } B \text{ at point of contact before impact ;}$$

$$a_1 \omega_1 = v_1 \quad = \text{linear velocity of } A \text{ at point of contact after impact ;}$$

$$a_2 \omega_2 = v_2 \quad = \text{linear velocity of } B \text{ at point of contact after impact ;}$$

$$\frac{I_1 \epsilon_1^2}{2g} = \left( \frac{I_1}{a_1^2} \right) \frac{c_1^2}{2g} = \text{actual energy of } A \text{ before impact ;}$$

$$\frac{I_2 \epsilon_2^2}{2g} = \left( \frac{I_2}{a_2^2} \right) \frac{c_2^2}{2g} = \text{actual energy of } B \text{ before impact ;}$$

$$\frac{I_1 \omega_1^2}{2g} = \left( \frac{I_1}{a_1^2} \right) \frac{v_1^2}{2g} = \text{actual energy of } A \text{ after impact ;}$$

$$\frac{I_2 \omega_2^2}{2g} = \left( \frac{I_2}{a_2^2} \right) \frac{v_2^2}{2g} = \text{actual energy of } B \text{ after impact ;}$$

Hence it follows that we have the case explained in § 112 for imperfectly elastic impact, provided only we write

$$\frac{I_1}{a_1^2} \text{ instead of } m_1 g \quad \text{and} \quad \frac{I_2}{a_2^2} \text{ instead of } m_2 g.$$

Hence we shall have

$$\omega_1 = \epsilon_1 - a_1(a_1\epsilon_1 - a_2\epsilon_2) \frac{I_2}{I_1 a_1^2 + I_2 a_2^2} (1 + e), \quad (1)$$

$$\omega_2 = \epsilon_2 + a_2(a_1\epsilon_1 - a_2\epsilon_2) \frac{I_1}{I_1 a_1^2 + I_2 a_2^2} (1 + e), \quad (2)$$

The case of perfect elasticity is obtained by making  $e = 1$ .

The case of total lack of elasticity is obtained by making  $e = 0$ .

In the latter case the loss of energy is

$$\frac{(a_1\epsilon_1 - a_2\epsilon_2)^2}{2} \frac{I_1 I_2}{I_1 a_1^2 + I_2 a_2^2}, \quad (3)$$

as can be seen by substituting the proper values in equation (8), § 112.

## CHAPTER III.

## ROOF-TRUSSES.

§ 117. **Definitions and Remarks.** — *The term "truss" may be applied to any framed structure intended to support a load.*

In the case of any truss, the external loads may be applied only at the joints, or some of the truss members may support loads at points other than the joints.

In the latter case those members are subjected, not merely to direct tension or compression, but also to a bending-action, the determination of which we shall defer until we have studied the mode of ascertaining the stresses in a loaded beam; and we shall at present confine ourselves to the consideration of the direct stresses of tension and compression.

For this purpose any loads applied between two adjacent joints must be resolved into two parallel components acting at those joints, and the truss is then to be considered as loaded at the joints. By this means we shall obtain the entire stresses in the members whenever the loads are concentrated at the joints; and, when certain members are loaded at other points, our results will be the direct tensions and compressions of these members, leaving the stresses due to bending yet to be determined.

*A tie is a member suited to bear only tension.*

*A strut is a member suited to bear compression.*

§ 118. **Frames of Two Bars.** — Frames of two bars may consist, (1) of two ties (Fig. 69), (2) of two struts (Fig. 70), (3) of a strut and a tie (Fig. 71).

CASE I. *Two Ties* (Fig. 69). — Let the load be represented graphically by  $CF = W$ . Then if we resolve it into two components,  $CD$  and  $CE$ , acting along  $CB$  and  $CA$  respectively,  $CD$  will represent graphically the pull or tension in the tie  $CB$ , and  $CE$  that in the tie  $CA$ .

FIG. 69.

The force acting on  $CB$  at  $B$  is equal and opposite to  $CD$ , while that acting on  $CA$  at  $A$  is equal and opposite to  $CE$ .

To compute these stresses analytically, we have

$$CE = CF \frac{\sin CFE}{\sin CEF} = W \frac{\sin i}{\sin(i + i_1)},$$

$$CD = CF \frac{\sin CFD}{\sin CDF} = W \frac{\sin i_1}{\sin(i + i_1)}.$$

CASE II. *Two Struts* (Fig. 70). — Let the load be represented graphically by  $CF = W$ .

Then will the components  $CD$  and  $CE$  represent the thrusts in the struts  $CB$  and  $CA$  respectively, and the re-actions of the supports at  $B$  and  $A$  will be equal and opposite to them. For analytical solution, we derive from the figure

FIG. 70.

$$CE = W \frac{\sin i_1}{\sin(i + i_1)}, \quad CD = W \frac{\sin i}{\sin(i + i_1)}.$$

CASE III. *A Strut and a Tie* (Fig. 71). — Let the load be represented graphically by  $CF = W$ . Resolve it, as before, into components along the members of the truss. Then will

$CE$  represent the tension in the tie  $AC$ , and  $CD$  will represent the thrust in the strut  $BC$ ; and we may deduce the analytical formulæ as before.

FIG. 71.

### § 119. Stability for Lateral Deviations.

— In Case I, if the joint  $C$  be moved a little out of the plane of the paper, the load at  $C$  has such a direction that it will cause the truss to rotate around  $AB$  so as to return to its former position; hence such a frame is stable as regards lateral deviations.

In Case II the effect of the load, if  $C$  were moved a little out of the plane of the paper, would be to cause rotation in such a way as to overturn the truss; hence such a frame is unstable as regards lateral deviations.

In Case III the stability for lateral deviations will depend upon whether the load  $CF = W$  is parallel to  $AB$ , is directed away from it or towards it. If the first is the case (i.e., if  $A$  is the point of suspension of the tie), the frame is neutral, as the load has no effect, either to restore the truss to its former position, or to overturn it; if the second is the case (i.e., if  $A_1$  is the point of suspension of the tie), the truss is stable; and, if the third is the case (i.e., if  $A_2$  is the point of suspension of the tie), it is unstable as regards lateral deviations.

§ 120. General Methods for Determining the Stresses in Trusses. — In the determination of the stresses as above, it would have been sufficient to construct only the triangle  $CFD$  by laying off  $CF = W$  to scale, and then drawing  $CD$  parallel to  $CB$ , and  $FD$  parallel to  $CA$ , and the triangle  $CFD$  would have given us the complete solution of the problem. Moreover, the determination of the supporting forces of any truss, and of the stresses in the several members, is a question of equilibrium.

Adopting the following as definitions, viz., —

*External forces* are the loads and supporting forces,

*Internal forces* are the stresses in the members :

we must have

1°. The external forces must form a balanced system ; i.e., the supporting forces must balance the loads.

2°. The forces (external and internal) acting at each joint of the truss must form a balanced system ; i.e., the external forces (if any) at the joint must be balanced by the stresses in the members which meet at that joint.

3°. If any section be made, dividing the truss into two parts, the external forces which act upon that part which lies on one side of the section, must be balanced by the forces (internal) exerted by that part of the truss which lies on the other side of the section, upon the first part.

The above three principles, the triangle, and polygon of forces, and the conditions of equilibrium for forces in a plane, enable us to determine the stresses in the different members of roof and bridge trusses.

§ 121. **Triangular Frame.** — Given the triangular frame  $ABC$  (Fig. 72), and given the load  $W$  at  $C$  in magnitude and direction, given also the direction of the supporting force at  $B$ , to find the magnitude of this supporting force, the magnitude and direction of the other supporting force, and the stresses in the members.

**SOLUTION.** — Join  $A$  with  $D$ , the point of intersection of the line of direction of the load and the line  $BE$ . Then will  $DA$  be the direction of the other supporting force ; for the three external forces, in order to form a balanced system, must meet in a point, except when they are parallel. Then draw  $ab$  to scale, parallel to  $CD$  and equal to  $W$ . From

FIG. 72.

$a$  draw  $ac$  parallel to  $BD$ , and from  $b$  draw  $bc$  parallel to  $AD$ ; then will the triangle  $abca$  be the triangle of external forces, the sides  $ab$ ,  $bc$ , and  $ca$ , taken in order, representing respectively the load  $W$ , the supporting force at  $A$ , and the supporting force at  $B$ .

Then from  $a$  draw  $ad$  parallel to  $BC$ , and from  $c$  draw  $cd$  parallel to  $AB$ ; then will the triangle  $acd$  be the triangle of forces for the joint  $B$ , and the sides  $ca$ ,  $ad$ , and  $dc$ , taken in order, will represent respectively the supporting force at  $B$ , the force exerted by the bar  $BC$  at the point  $B$ , and the force exerted by the bar  $AB$  at the point  $B$ .

Since, therefore, the force  $ad$  exerted by the bar  $CB$  at  $B$  is directed *away from* the bar, it follows that  $CB$  is in compression; and, since the force  $dc$  exerted by the bar  $AB$  at  $B$  is directed *towards* the bar, it follows that  $AB$  is in tension.

In the same way  $bdc$  is the triangle of forces for the point  $A$ ; the sides  $bc$ ,  $cd$ , and  $db$  representing respectively the supporting force at  $A$ , the force exerted by the bar  $AB$  at  $A$ , and the force exerted by the bar  $AC$  at  $A$ .

FIG. 73.

Fig. 73 shows the case when the supporting forces meet the load-line above, instead of below, the truss.

§ 122. **Triangular Frame with Load and Supporting Forces Vertical.**—Fig. 74 shows the construction when the load and also the supporting forces are vertical. In this case

the diagram becomes very much simplified, the triangle of external forces  $abd$  becoming a straight line. The diagram is otherwise constructed just like the last one.

§ 123. **Bow's Notation.**

— The notation devised by Robert H. Bow very much simplifies the construction of the stress diagrams of roof-trusses.

FIG. 74.

This notation is as follows: Let the radiating lines (Fig. 75) represent the lines of action of a system of forces in equilibrium, and let the polygon  $abcdefa$  be the polygon representing these forces in magnitude and direction;

FIG. 75.

then denote the sides of the polygon in the ordinary way, by placing small letters at the vertices, but denote the radiating lines by capital letters placed in the angles. Thus the line  $AB$  is the line of direction of the

force  $ab$ , etc. In applying the notation to roof-trusses, we letter the truss with capital letters in the spaces, and the stress diagram with small letters at the vertices. If, then, in drawing the polygon of equilibrium for any one joint of the truss, we take the forces always in the same order, proceeding always in right-handed or always in left-handed rotation, we shall be led to the simplest diagrams. Hereafter this notation will be used exclusively in determining the stresses in roof-trusses.

§ 124. **Isosceles Triangular Frame: Concentrated Load** (Fig. 76.) — Let the load  $W$  act at the apex, the supporting

forces being vertical; each will be equal to  $\frac{1}{2}W$ : hence the polygon of external forces will be the triangle  $abc$ , the sides of

FIG. 76.

which,  $ab$ ,  $bc$ , and  $ca$ , all lie in one straight line. Then begin at the left-hand support, and proceed again in right-handed rotation, and we have as the triangle of forces at this joint  $cad$ , the forces  $ca$ ,  $ad$ , and  $dc$ , these being respectively the supporting force, the stress in  $AD$ , and that in  $DC$ ; the directions of these forces being indicated by

the order in which the letters follow each other: thus,  $ca$  is an upward force,  $ad$  is a downward force; and, this being the force exerted by the bar  $AD$  at the left-hand support, we conclude that the bar  $AD$  is in compression. Again:  $dc$  is directed towards the right, or towards the bar itself, and hence the bar  $DC$  is in tension. The triangle of forces for the other support is  $bcd$ , and that for the apex  $abd$ .

#### § 125. Isosceles Triangular Frame: Distributed Load. —

Let the load  $W$  be uniformly distributed over the two rafters  $AF$  and  $FB$  (Fig. 77); then will these two rafters be subjected to a direct stress, and also to a bending action: and if we resolve the load on each rafter into two components at the ends of the rafter, then, considering these components as the loads at the joints, we shall determine correctly by our diagram the direct stresses in all the bars of the truss.

FIG. 77.

The load distributed over  $AF$  is  $\frac{W}{2}$ ; and of this, one-half is

the component at the support, and one-half at the apex, and similarly for the other rafter. This gives as our loads,  $\frac{W}{4}$  at each support, and  $\frac{W}{2}$  at the apex. The polygon of external forces is  $eaabcde$ , where the sides are as follows:—

$$ea = \frac{W}{4}, \quad ab = \frac{W}{2}, \quad bc = \frac{W}{4}, \quad cd = \frac{W}{2}, \quad de = \frac{W}{2}.$$

Then, beginning at the left-hand support, we shall have for the polygon of forces the quadrilateral  $deafd$ , where  $de = \frac{W}{2}$  = supporting force,  $ea = \frac{W}{4}$  = downward load at support,  $af$  = stress in  $AF$  (compression),  $fd$  = stress in  $FD$  (tension). The polygon for the apex is  $abf$ , and that for the right-hand support  $cdfbc$ .

§ 126. **Polygonal Frame.**— Given a polygonal frame (Fig. 78) formed of bars jointed together at the vertices of the angles, and free to turn on these joints, it is evident, that, in order that the frame may retain its form, it is necessary that the directions of, and the proportions between, the loads at the different joints, should be specially adapted to the given form: otherwise the frame will change its form. We will proceed to solve the following problem: Given the form of the frame, the magnitude of one load as  $AB$ , and the direction of all the external forces (loads and supporting forces) except one, we shall have sufficient data to determine the magnitudes of all,

FIG. 78.

and the direction of the remaining external forces, and also the stresses in the bars

Let the direction of all the loads be given, and also that of the supporting force  $EF$ , that of the supporting force  $AF$  being thus far unknown; and let the magnitude of  $AB$  be given. Then, beginning at the joint  $ABG$ , we have for triangle of forces  $abg$  formed by drawing  $ab \parallel$  and  $= AB$ , then drawing  $ga \parallel AG$ , and  $bg \parallel BG$ ;  $ga$  and  $bg$  both being thrusts. Then, passing to the joint  $BCG$ , we have the thrust in  $BG$  already determined, and it will in this case be represented by  $gb$ . If, now, we draw  $bc \parallel BC$ , and  $gc \parallel GC$ , we shall have determined the load  $BC$  as  $bc$ , and we shall have  $cg$  and  $gb$  as the thrusts in  $CG$  and  $GB$  respectively. Continuing in the same way, we obtain the triangles  $gcd$ ,  $gde$ , and  $gfe$ , thus determining the magnitudes of the loads  $cd$ ,  $de$ , and of the supporting force  $ef$ ; and then the triangle  $gaf$ , formed by joining  $a$  and  $f$ , gives us  $af$  for the magnitude and direction of the left-hand support. The polygon  $abcdefa$  of external forces is called the *Force Polygon*, while the frame itself is called the *Equilibrium Polygon*.

§ 127. **Polygonal Frame with Loads and Supporting Forces Vertical.**—In this case (Fig. 79) we may give the

FIG. 79.

form of the frame and the magnitude of one of the loads, to determine the other loads and the supporting forces, and also the stresses in the bars; or we may give the form of the frame and the magnitude of the resultant of the loads, to find the loads and supporting forces. In the former case let the load  $AB$  be given. Then, proceeding in

the same way as before, we find the diagram of Fig. 79; the polygon of external forces  $abcdefa$  falling all in one straight line.

If, on the other hand, the whole load  $ae$  be given, we observe that this is borne by the stresses in the extreme bars  $AG$  and  $GE$ ; hence, drawing  $ag \parallel AG$ , and  $eg \parallel EG$ , we find  $eg$  and  $ga$  as the stresses in  $EG$  and  $GA$  respectively. Then, proceeding to the joint  $ABG$ , we find, since  $ga$  is the force exerted by  $GA$  at this point, that, drawing  $gb \parallel GB$ , we shall have  $ab$  as the part of the load acting at the joint  $ABG$ , etc.

§ 128. **Funicular Polygon.** — If the frame of Fig. 79 be inverted, we shall have the case of Fig. 80, where all the bars, except  $FG$ , are subjected to tension;  $FG$  itself being subjected to compression. The construction of the diagram of stresses being entirely similar to that already explained for Fig. 79, the explanation will not be repeated here. If the compression piece be omitted, the case becomes that of a chain hung at the upper joints (the supporting forces then becoming identical with the tensions in the two extreme bars), the line  $gf$  would then be omitted from the diagram, and the polygon of external forces would become  $abcdega$ .

FIG. 80.

at the upper joints (the supporting forces then becoming identical with the tensions in the two extreme bars), the line  $gf$  would then be omitted from the diagram, and the polygon of external forces would become  $abcdega$ .

§ 129. **Triangular Truss: Wind Pressure.** — Inasmuch as the pressure of the wind upon a truss is assumed to be normal to the rafter on which it blows, we will next consider the case of a triangular truss with the load distributed over one rafter only, and normal to the rafter.

There may be three cases:—

1°. When there is a roller under one end, and the wind blows from the other side.

2°. When there is a roller under one end, and the wind blows from the side of the roller.

3°. When there is no roller under either end.

The last arrangement should always be avoided except in small and unimportant constructions; for the presence of a roller under one end is necessary to allow the truss to change its length with the changes of temperature, and to prevent the stresses that would occur if it were confined.

CASE I. — Using Bow's notation, we have (Fig. 81) the

FIG. 81.

whole load represented in the diagram by  $db$ . Its resultant acts at the middle of the rafter  $AE$ , whereas the supporting force at the right-hand end is (in consequence of the presence of the roller) vertical. Hence, to find the line of action of the other supporting force, produce the line of action of the load till it meets a vertical line drawn

through the roller, and join their point of intersection with the support where there is no roller. We thus obtain  $CD$  as the line of action of the left-hand support.

We can now determine the magnitude of the supporting forces  $bc$  and  $cd$  by constructing the triangle  $bcd$  of external forces.

Now resolve the normal distributed force  $db$  into two single forces (equal to each other in this case),  $da$  and  $ab$  respectively, acting at the left-hand support and at the apex.

Now proceed to the left-hand support. We find four forces in equilibrium, of which two are entirely known; viz.,  $cd$  and  $da$ : hence, constructing the quadrilateral  $cdaec$ , we have  $ae$  as the thrust in  $AE$ , and  $ec$  as the tension in  $EC$ .

Next proceed to the apex, and construct the triangle of equilibrium  $abea$ , and we obtain  $be$  as the thrust in  $BE$ .

The triangle  $bceb$  is then the triangle of equilibrium for the right-hand support.

CASE II. — In this case (Fig. 82) we follow the same method of procedure, only the point of intersection of the load and supporting forces

FIG. 82.

is above, instead of below, the truss. The figure explains itself so fully that it is unnecessary to explain it here.

FIG. 83.

CASE III. — In this case the supports are capable of exerting resistance in any direction whatever; so that, if any circumstance should determine the direction of one of them, that of the other would be determined also. When there is no such circumstance, it is customary to assume them parallel to the load (Fig. 83). Making this assumption, we begin by dividing the line  $db$ , which represents the load, into two parts, inversely

proportional to the two segments into which the line of action of the resultant of the load (the dotted line in the figure) divides the line  $EC$ . We thus obtain the supporting forces  $bc$  and  $cd$ , and  $bcd$  is the triangle of external forces. We then follow the same method as in the preceding cases.

§ 130. **General Determination of the Stresses in Roof-Trusses.** — In order to compute the stresses in the different members of a roof-truss, it is necessary first to know the amount and distribution of the load.

This consists generally of —

- 1°. The weight of the truss itself.
- 2°. The weight of the purlins, jack-rafters, and superincumbent roofing, as the planks, slate, shingles, felt, etc.
- 3°. The weight of the snow.
- 4°. The weight of the ceiling of the room immediately below if this is hung from the truss, or the weight of the floor of the loft, and its load, if it be used as a room.
- 5°. The pressure of the wind; and this may blow from either side.
- 6°. Any accidental load depending on the purposes for which the building is used. As an instance, we might have the case where a system of pulleys, by means of which heavy weights are lifted, is attached to the roof.

In regard to the first two items, and the fourth, whenever the construction is of importance, the actual weights should be determined and used. In so doing, we can first make an approximate computation of the weight of the truss, and use it in the computation of the stresses; the weights of the ceiling or of the floor below being accurately determined. After the stresses in the different members have been ascertained by the use of these loads, and the necessary dimensions of the members determined, we should compute the actual weight of the truss; and if our approximate value is sufficiently different from the true value to warrant it, we should compute again

the stresses. This second computation will, however, seldom be necessary.

In making these computations, the weights of a cubic foot of the materials used will be needed; and average values are given in the following table with sufficient accuracy for the purpose.

| WEIGHT OF SOME BUILDING MATERIALS PER CUBIC FOOT. | Pounds.    | WEIGHT OF SLATING PER SQUARE FOOT.<br>According to Trautwine. | Pounds.           |
|---|------------|---|-------------------|
| <b>TIMBER.</b>                                    |            |   |                   |
| Chestnut . . . . .                                | 41         | $\frac{1}{4}$ inch thick on laths . . .                       | 4.75              |
| Hemlock . . . . .                                 | 25         | $\frac{1}{4}$ " " " 1-inch boards .                           | 6.75              |
| Maple . . . . .                                   | 41         | $\frac{1}{4}$ " " " 1 $\frac{1}{4}$ " " .                     | 7.30              |
| Oak, live . . . . .                               | 59         | $\frac{3}{8}$ " " " laths . . .                               | 7.00              |
| Oak, white . . . . .                              | 49         | $\frac{3}{8}$ " " " 1-inch boards,                            | 9.00              |
| Pine, white . . . . .                             | 25 to 30   | $\frac{3}{8}$ " " " 1 $\frac{1}{4}$ " " .                     | 9.55              |
| Pine, yellow, Southern . .                        | 45         | $\frac{1}{2}$ " " " laths . . .                               | 9.25              |
| Spruce . . . . .                                  | 25 to 30   | $\frac{1}{2}$ " " " 1-inch boards,                            | 11.25             |
|   |            | $\frac{1}{2}$ " " " 1 $\frac{1}{4}$ " " .                     | 11.80             |
|   |            | With slating-felt add . . .                                   | $\frac{1}{4}$ lb. |
|   |            | With $\frac{1}{4}$ -inch mortar add . .                       | 3 lbs.            |
| <b>IRON.</b>                                      |            |   |                   |
| Iron, cast . . . . .                              | 450        | <b>NUMBER OF NAILS IN ONE POUND.</b>                          | <b>No.</b>        |
| Iron, wrought . . . . .                           | 480        |   |                   |
| Steel . . . . .                                   | 490        |   |                   |
| <b>OTHER SUBSTANCES.</b>                          |            |   |                   |
| Asphaltum . . . . .                               | 80 to 90   | 3-penny . . . . .   | 450               |
| Mortar, hardened . . . .                          | 103        | 4 " . . . . .   | 340               |
| Snow, freshly fallen . . .                        | 5 to 12    | 6 " . . . . .   | 150               |
| Snow, compacted by rain .                         | 15 to 50   | 8 " . . . . .   | 100               |
| Slate . . . . .                                   | 140 to 180 | 10 " . . . . .  | 60                |
|   |            | 12 " . . . . .  | 40                |
|   |            | 20 " . . . . .  | 25                |

As to the weight of the snow upon the roof, Stoney recommends the use of 20 pounds per square foot in moderate climates; and this would seem to the writer to be borne out by the experiments of Trautwine as recorded in his handbook,

although Trautwine himself considers 12 pounds per square foot as sufficient.

§ 131. **Wind Pressure.** — The wind pressure, as has been stated, is not a vertical force, but is always assumed as acting normal to the roof on that side from which the wind blows. In order to determine the magnitude of this pressure, it has been advocated by some, to resolve the force of the wind into two components, one acting along, and one at right angles to, the roof. This method is, however, incorrect, because the moving air, striking against other particles of air, is deviated from its course, and the air, after striking the roof, cannot escape freely, but meets with the resistance of the surrounding air. Hence we must resort to experiment to determine the amount of the pressure due to the wind. The experiments of Hutton, according to Greene, give, for the pressure upon a surface whose inclination to the horizon is  $i$ , the value

$$P \sin i^{1.84 \cos i - 1}$$

where  $P$  is the pressure which would be exerted on the surface if normal to the wind; and, taking the maximum force of the wind as 40 pounds per square foot, he gives for the normal pressures on surfaces inclined to the horizon the following:—

| INCLINATION. | NORMAL PRESSURE. | INCLINATION. | NORMAL PRESSURE. |
|--------------|------------------|--------------|------------------|
| 5°           | 5.2              | 35°          | 30.1             |
| 10°          | 9.6              | 40°          | 33.4             |
| 15°          | 14.0             | 45°          | 36.1             |
| 20°          | 18.3             | 50°          | 38.1             |
| 25°          | 22.5             | 55°          | 39.6             |
| 30°          | 26.5             | 60°          | 40               |

and for all steeper angles 40.

Later experiments show that these numbers are too small: stresses of 70 lbs. per square foot have been registered on vertical surfaces; but we have no systematic set of tests on the subject.

§ 132. **Approximate Estimation of the Load.**—In all important constructions, the estimates of the loads should be made as above described. For smaller constructions, and for the purposes of a preliminary computation in all cases, we only estimate the roof-weight roughly; and some authors even assume the wind pressure as a vertical force.

Trautwine recommends the use of the following figures for the total load per square foot, including wind and snow, when the span is 75 feet or less:—

|  |         |
|--|---------|
| Roof covered with corrugated iron, unboarded . . .           | 28 lbs. |
| Roof plastered below the rafters . . . . .                   | 38 "    |
| Roof, corrugated iron on boards . . . . .                    | 31 "    |
| Roof plastered below the rafters . . . . .                   | 41 "    |
| Roof, slate, unboarded or on laths . . . . .                 | 33 "    |
| Roof, slate, on boards $1\frac{1}{2}$ inches thick . . . . . | 35 "    |
| Roof, slate, if plastered below the rafters . . . . .        | 46 "    |
| Roof, shingles on laths . . . . .                            | 30 "    |
| Roof plastered below rafters or below tie-beam . . .         | 40 "    |
| From 75 to 100 feet, add 4 lbs. to each.                     |         |

§ 133. **Distribution of the Loads.**—The methods for determining the stresses, which will be used here, give correct results only when the loads are concentrated at joints, and are not distributed over any members of the truss.

In constructions of importance, this concentration of the loads at the joints should always be effected if possible; because, when this is the case, the stresses in the members of the truss can be, if properly fitted, obliged to resist only stresses of direct tension, or of direct compression; but, when there is a load distributed over any member of the truss, that member, in addition to the direct compression or direct tension, is subjected to a bending-stress. The effect of this bending

cannot be discussed until we have studied the theory of beams. Nevertheless, it is a fact that we have no experimental knowledge of the behavior of a piece under combined compression and bending; and we know that when certain pieces are to resist bending, in addition to tension, they must be made much larger in proportion than is necessary when they bear tension only.

FIG. 84.

The manner in which this concentration of the loads is effected, is shown in Fig. 84, which is intended to represent one of a series of trusses that supports a roof, the rafters being the two lower ones in the figure. Resting on two consecutive trusses, and extending from one to the other, are beams called purlins, which should be placed only above the joints of the truss, and which are shown in cross-section in the figure. On these purlins are supported the jack-rafters parallel to the rafters, and at sufficiently frequent intervals to support suitably the plank and superincumbent roofing-materials.

By this means we secure that the entire bending-stress comes upon the jack-rafters and purlins, and that the rafters proper are subjected only to a direct compression. When, however, the load is distributed, i.e., when the roofing rests directly on the rafters, or when the purlins are placed at points other than the joints, the bending-stress should be taken into account; and while the methods to be developed here will give the stresses

in all the members that are not subjected to bending, the bending-stress may be largely in excess of the direct stress in those pieces that are subjected to bending. How to take this into account will be explained later.

Another important item to consider is, that, in constructions of importance, a roller should be placed under one end of the truss to allow it to move with the change of temperature; as otherwise some of the members will be either bent, or at least subjected to initial stresses. The presence of a roller obliges the supporting force at that point to be vertical, whether the load be vertical or inclined.

It is customary, and does not entail any appreciable error, to consider the weight of the truss itself, as well as that of the superincumbent load, as concentrated at the upper joints; i.e., those on the rafters.

In the case of a ceiling on the room below, or of a loft whose floor rests on the lower joints, we must, of course, account the proper load as resting on the lower joints.

§ 134. **Direct Determination of the Stresses.** — This, as we have seen, is merely a question of equilibrium of forces in a plane, where certain forces acting are known, and others are to be determined.

As to the methods of solution, we might adopt —

1°. A graphical solution, laying off the loads to scale, and constructing the diagram by the use of the propositions of the polygon, and the triangle of forces, and then determining the results by measuring the lines representing the stresses to the same scale.

2°. An analytical solution, imposing the analytical conditions of equilibrium, as given under the "Composition of Forces," between the known and unknown forces.

3°. A third method is to construct the diagram as in the graphical solution, but then, instead of determining the results by measuring the resulting lines to scale, to compute the un-

known from the known lines of the diagram by the ordinary methods of trigonometry.

The first, or purely graphical, method, is one which has received a very large amount of attention of late years, and in which a great deal of progress has been made. It is, doubtless, very convenient for a skilled draughtsman, and especially convenient for one who, though skilled in draughting, is not free with trigonometric work; but it seems to me, that, when the results are determined by computation from the diagram, there is less chance of a slight error in some unfavorable triangle vitiating all the results. I am therefore disposed to recommend for roof-trusses the third method.

In the case of bridge-trusses, on the other hand, I believe the graphical not to be as convenient as a purely analytic method.

§ 135. **Roof-Trusses.** — In what follows, the graphical solutions will be explained with very little reference to the trigonometric work, as that varies in each special case, and to one who has a reasonable familiarity with the solution of plane triangles, it will present no difficulty; whereas to deduce the formulæ for each case would complicate matters very much. Proceeding to special examples, let us take, first, the truss shown in Fig. 85, and let the vertical load upon it be  $W$  uniformly distributed over the top of the roof, the purlins being at the joints on the rafters.

The loads at the several joints will then be as follows, viz. (Fig. 85a), —

$$ab = kl = \frac{W}{16}, \quad bc = cd = de = ef = fg = gh = hk = \frac{W}{8}.$$

Then the supporting forces will be

$$lm = ma = \frac{W}{2}.$$

We thus have, as polygon of external forces,  $abcdefghklma$ .

Now proceed to either support, say, the left-hand one; and there we have the two forces  $ab$  and  $ma$  known, while  $by$  and  $ym$  are unknown. We then construct the quadrilateral  $maby$  in the figure, and thus determine  $by$  and  $ym$ . As to whether

FIG. 85.

these represent thrust or tension, we need only remember that they are the forces exerted by the respective bars at the joints: and, since  $by$  is directed away from the bar  $BY$ , this bar is in compression; whereas,  $ym$  being directed towards the bar  $YM$ , that bar is in tension.

FIG. 85a.

FIG. 85b.

FIG. 85c.

Having determined these two stresses, we next proceed to another joint, where we have only two unknown forces. Take the joint at which the load  $bc$  acts, and we have as known quantities the load  $bc$ , and also the force exerted by the bar  $YB$ , which is in compression. This force is now directed away from the bar, and hence is represented by  $y\bar{b}$ . The unknown forces are the stresses in  $CX$  and  $XY$ . Hence we construct the quadrilateral  $cxy\bar{b}c$ ; and we thus determine the stresses in  $CX$  and  $XY$  as  $c\bar{x}$  and  $x\bar{y}$ , both being thrusts.

Next proceed to the joint  $YXW$ , and construct the quadrilateral  $myxwm$ , and thus determine the tension  $xw$  and the tension  $w\bar{m}$ .

Next proceed to the joint where  $cd$  acts, and so on. We thus obtain the diagram (Fig. 85a) giving all the stresses.

The truss in the figure was constructed with an angle of  $30^\circ$  at the base, and hence gives special values in accordance with that angle.

In order to show how we may compute the stresses from the diagram, the computation will be given.

From triangle  $bmy$ , we have  $bm = \frac{7}{16} W$

$$\therefore ym = \frac{7}{16} W \cot 30^\circ = \frac{7\sqrt{3}}{16} W$$

$$by = \frac{7}{16} W \operatorname{cosec} 30^\circ = \frac{7}{8} W = ky.$$

From the triangle  $umc$ , we have  $cm = \frac{5}{16} W$ ,

$$um = \frac{5\sqrt{3}}{16} W,$$

$$yw = \frac{1}{2} yu = \frac{1}{2} \left( \frac{2}{16} W \sqrt{3} \right) = \frac{\sqrt{3}}{16} W,$$

$$\begin{aligned}
 yx &= yw \sec 30^\circ = \left( \frac{\sqrt{3}}{16} W \right) \frac{2}{\sqrt{3}} = \frac{W}{8} = xv = vt, \\
 xw &= \frac{1}{2} yx = \frac{W}{16}, \quad uv = \frac{W}{8}, \quad st = 2 \left( \frac{3}{16} W \right) = \frac{3}{8} W, \\
 wv &= \sqrt{(wu)^2 + (uv)^2} = W \sqrt{\frac{3}{256} + \frac{4}{256}} = \frac{\sqrt{7}}{16} W, \\
 ut &= \sqrt{(wu)^2 + \left( \frac{1}{2} st \right)^2} = W \sqrt{\frac{3}{256} + \frac{9}{256}} = \frac{\sqrt{3}}{8} W, \\
 cx &= um \sec 30^\circ = \left( \frac{3\sqrt{3}}{8} W \right) \frac{2}{\sqrt{3}} = \frac{3}{4} W, \\
 vd &= um \sec 30^\circ = \left( \frac{5\sqrt{3}}{16} W \right) \frac{2}{\sqrt{3}} = \frac{5}{8} W, \\
 et &= \left( \frac{\sqrt{3}}{4} W \right) \frac{2}{\sqrt{3}} = \frac{1}{2} W.
 \end{aligned}$$

Hence we shall have for the stresses, —

| RAFTERS (compression).     |                             | VERTICALS (tension).           |                            |
|----------------------------|-----------------------------|--------------------------------|----------------------------|
| $by = kn$                  | $= \frac{7}{8} W.$          | $xw = op$                      | $= \frac{W}{16}.$          |
| $cx = ho$                  | $= \frac{3}{4} W.$          | $vn = qr$                      | $= \frac{W}{8}.$           |
| $dv = gq$                  | $= \frac{5}{8} W.$          | $ts =$                         | $\frac{3}{8} W.$           |
| $ct = fs$                  | $= \frac{1}{2} W.$          |                                |                            |
| HORIZONTAL TIES (tension). |                             | DIAGONAL BRACES (compression). |                            |
| $my = mn$                  | $= \frac{7\sqrt{3}}{16} W.$ | $xy = ou$                      | $= \frac{W}{8}.$           |
| $mw = mp$                  | $= \frac{3\sqrt{3}}{8} W.$  | $wv = qp$                      | $= \frac{\sqrt{7}}{16} W.$ |
| $mu = mr$                  | $= \frac{5\sqrt{3}}{16} W.$ | $tu = sr$                      | $= \frac{\sqrt{3}}{8} W.$  |

Next, as to the stresses due to wind pressure, we will suppose that there is a roller under the left-hand end of the truss, and none under the right-hand end; and we will proceed to determine the stresses due to wind pressure.

First, suppose the wind to blow from the left-hand side of the truss, and let the total wind pressure be (Fig. 85*b*)  $af = W_1$ . The resultant, of course, acts along the dotted line drawn perpendicular to the left-hand rafter at its middle point, as shown in Fig. 85.

The left-hand supporting force will be vertical: hence, producing the above-described dotted line, and a vertical through the roller to their intersection, and joining this point with the right-hand end of the truss, we have the direction of the right-hand supporting force. In this case, since the angle of the truss is  $30^\circ$ , the line of action of the right-hand supporting force coincides in direction with the right-hand rafter. We now construct the triangle of external forces  $afm$ , and we obtain the supporting forces  $fm$  and  $ma$ . We then have, as the loads at the joints,

$$ab = \frac{W_1}{8} = ef,$$

$$bc = \frac{W_1}{4} = cd = de.$$

Then proceed as before to the left-hand joint; and we find that two of the four forces acting there are known, viz.,  $ma$  and  $ab$ , and two are unknown, viz., the stresses in  $BY$  and  $YM$ . Then construct the quadrilateral  $mabym$ , and we have the stresses  $by$  and  $ym$ ; the first being compression and the second tension, as shown by reasoning similar to that previously adopted.

Then pass to the next joint on the rafter, and construct the quadrilateral  $ybcxy$ , where  $yb$  and  $bc$  are already known, and we obtain  $cx$  and  $xy$ ; and so proceed as before from joint to joint,

remembering, that, in order to be able to construct the polygon of forces in each case, it is necessary that only two of the forces acting should be unknown.

When the wind blows from the other side, we shall obtain the diagram shown in Fig. 85c.

After having determined the stresses from the vertical load diagram and those from the two wind diagrams, we should, in order to obtain the greatest stress that can come on any one member of the truss, add to the stress due to the vertical load the greater of the stresses due to the wind pressure.

§ 136. **Roof-Truss with Loads at Lower Joints.** — In Fig. 86 is drawn a stress diagram for the truss shown in Fig. 84 on the supposition that there is also a load on the lower joints. In this case let  $W$  be the whole load of the truss, except the ceiling, and  $W_1$  the weight of the ceiling below; the latter being supported at the lower joints and on the two extreme vertical suspension rods. Then will the loads at the joints be as follows; viz., —

FIG. 86.

$$\begin{aligned}
 ab &= \frac{1}{8}(W + W_1) = kl, \\
 bc &= \frac{1}{8}(W + W_1) = hk, \\
 cd &= \frac{1}{8}W &= gh = de = fg = ef, \\
 mn &= \frac{1}{8}W_1 = rq &= on = qp = op.
 \end{aligned}$$

Observe that there is no joint at the lower end of either of the end suspension rods, but that whatever load is supported by these is hung directly from the upper joints, where  $bc$  and  $hk$  act.

We have also for each of the supporting forces  $lm$  and  $ra$

$$\frac{1}{2}(W + W_1).$$

Hence we have, for the polygon of external forces,

*abcdefghhklmnopqra,*

which is all in one straight line, and which laps over on itself.

In constructing the diagram, we then proceed in the same way as heretofore.

§ 137. **General Remarks.** — As to the course to be pursued in general, we may lay down the following directions:—

1°. *Determine all the external forces; in other words, the loads being known, determine the supporting forces.*

2°. *Construct the polygon of forces for each joint of the truss, beginning at some joint where only two of the forces acting at that joint are unknown.* This is usually the case at the support. Then proceed from joint to joint, bearing in mind that we can only determine the polygon of forces when the magnitudes of all but two sides are known.

3°. *Adopt a certain direction of rotation, and adhere to it throughout; i.e., if we proceed in right-handed rotation at one joint, we must do the same at all, and we shall thus obtain neat and convenient figures.*

4°. *Observe that the stresses obtained are the forces exerted by the bars under consideration, and that these are thrusts when they act away from the bars, and tensions when they are directed towards the bars.*

We will next take some examples of roof-trusses, and construct the diagrams of some of them, calling attention only to special peculiarities in those cases where they exist.

It will be assumed that the student can make the trigonometric computations from the diagram.

The scale of load and wind diagram will not always be the same; and the stress diagrams will in general be smaller than is advisable in using them, and very much too small if the

results were to be obtained by a purely graphical process without any computation.

The loads will in all cases be assumed to be distributed uniformly over the jack-rafters, or, in other words, concentrated at the joints.

Those cases where no stress diagram is drawn may be considered as problems to be solved.

§ 138. **Hammer-Beam Truss** (Fig. 94). — This form of truss is frequently used in constructions where architectural effect is the principal consideration rather than strength. It is not an advantageous form from the point of view of strength,

FIG. 94.

FIG. 94a.

FIG. 94b.

FIG. 94c.

for the absence of a tie-rod joining the two lower joints causes a tendency to spread out at the base, which tendency is usually counteracted by the horizontal thrust furnished by the buttresses against which it is supported.

When such a thrust is furnished (or were there a tie-rod), and the load is symmetrical and vertical, the bars are not all needed, and some of them are left without any stress. In the case in hand, it will be found that  $UV$ ,  $VM$ ,  $MQ$ , and  $QR$  are not needed. We must also observe that the effect of the curved members  $MY$ ,  $MV$ ,  $MQ$ , and  $MN$  on the other parts of the truss is just the same as though they were straight, as shown in the dotted lines. The curved piece, of course, has to be subjected to a bending-stress in order to resist the stress acting upon it. If, as is generally the case, the abutments are capable of furnishing all the horizontal thrust needed, it will first be necessary to ascertain how much they will be called upon to furnish. To do this, observe that we have really a truss similar to that shown in Fig. 92, supported on two inclined framed struts, of which the lines of resistance are the dotted lines (Fig. 94) 1 4 and 7 8, and that, under a symmetrical load, this polygonal frame will be in equilibrium, and, moreover, the curved pieces  $MV$  and  $MQ$  will be without stress, these only being of use to resist unsymmetrical loads, as the snow or wind.

Let the whole load, concentrated by means of the purlins at the joints of the rafters, be  $W$ . Then will the truss 4 6 7 have to bear  $\frac{1}{2}W$ , and this will give  $\frac{W}{4}$  to be supported at each of the points 4 and 7. Moreover, on the space 2 4 is distributed  $\frac{W}{4}$ , which has, as far as overturning the strut is concerned, the same effect as  $\frac{W}{8}$  at 2, and  $\frac{W}{8}$  at 4. Hence the load to be supported at 4 by the inclined strut is a vertical load equal to  $(\frac{1}{4} + \frac{1}{8})W = \frac{3}{8}W$ . We may then find the force that must be furnished by the abutment, or by the tie-rod, in either of the two following ways:—

1°. By constructing the triangle  $\gamma\delta\epsilon$  (Fig. 94a), with  $\gamma\delta = \frac{3}{8}W$ ,  $\gamma\epsilon \parallel I4$ , and  $\epsilon\delta$  parallel to the horizontal thrust of the abutment; then will  $\gamma\delta\epsilon$  be the triangle of forces at 1, and  $\epsilon\delta$  will be the thrust at 1.

2°. Multiply  $\frac{3}{8}W$  by the perpendicular distance from 4 to 1 2, and divide by the height of 4 above 1 8 for the thrust of the abutment; in other words, take moments about the point 1.

Now, to construct the diagram of stresses, let, in Fig. 94b, the loads be

$$ab, bc, cd, de, ef, fg, gh, hk, \text{ and } kl,$$

and let

$$ls = sa = \frac{1}{8}W$$

be the vertical component of the supporting force; let  $sm$  be the thrust of the abutment: then will  $lm$  and  $ma$  be the real supporting forces; and we shall have, for polygon of external forces,

$$abcdefghklma.$$

Then, proceeding to the joint 1, we obtain, for polygon of forces,

$$maym;$$

and, proceeding from joint to joint, we obtain the stresses in all the members of the truss, as shown in Fig. 94b.

It will be noticed that  $UV$  and  $RQ$  are also free from stress.

If we had no horizontal thrust from the abutment, and the supporting forces were vertical, the members  $MV$  and  $MQ$  would be called into action, and  $MY$  and  $MN$  would be inactive. To exhibit this case, I have drawn diagram 94c, which shows the stresses that would then be developed.  $AY$  and  $NL$  would become merely part of the supports.

In this latter case the stresses are generally much greater than in the former, and a stress is developed in  $UV$ .

§ 139. **Hammer-Beam Truss: Wind Pressure.** — Fig. 95 shows the stress diagram of the hammer-beam truss for wind pressure when there is no roller under either end, and when the wind blows from the left. A similar diagram would give the stresses when it blows from the right.

FIG. 95.

FIG. 95a.

The cases when there is a roller are not drawn: the student may construct them for himself.

§ 140. **Scissor-Beam Truss.** — We have already discussed two forms of scissor-beam truss in Figs. 90 and 91. These trusses having the right number of parts, their diagrams present no difficulty. Another form of the scissor-beam truss is shown in Fig. 96, and its diagram presents no difficulty.

FIG. 96.

FIG. 96a.

The only peculiarity to be noticed is, that, after having constructed the polygon of external forces,

$$abcdefma,$$

we cannot proceed to construct the polygon of equilibrium for one of the supports, because there are three unknown forces

there. We therefore begin at the apex  $CD$ , and construct the triangle of forces  $cdl$  for this point; then proceed to joint  $CB$ , and construct the quadrilateral

$bclkb$ ;

then proceed to the left-hand support, and obtain

$mabkgm$ ;

and so continue.

§ 141. **Scissor-Beam Truss without Horizontal Tie.** — Very often the scissor-beam truss is constructed without any horizontal tie, in which case it has the appearance of Fig. 97, where there is sometimes a pin at  $GKLH$  and sometimes not.

FIG. 97.

FIG. 97a.

FIG. 97b.

FIG. 97c.

In this case, if the abutments are capable of furnishing horizontal thrust to take the place of the horizontal tie of Fig. 96, we are reduced back to that case. If the abutments are not capable of furnishing horizontal thrust, we are then relying on the stiffness of the rafters to prevent the deformation of the truss; for, were the points  $BC$  and  $DE$  really joints, with pins, the deformation would take place, as shown in Fig. 97a or Fig. 97b, according as the two inclined ties were each made in one piece or in two (i.e., according as they are not pinned together at  $KH$ , or as they are pinned). This necessity of depending on the stiffness of the rafters, and the liability to deformation if they had joints at their middle points, become apparent as soon as we attempt to draw the diagram. Such an attempt is

made in Fig. 97c, where  $abcdefga$  is the polygon of external forces,  $gabkg$  the polygon of stresses for the left-hand support,  $kbcck$  that for joint  $BC$ . Then, on proceeding to draw the triangle of stresses for the vertex, we find that the line joining  $d$  and  $l$  is not parallel to  $DL$ , and hence that the truss is not stable. We ought, however, in this latter case, when the supporting forces are vertical, and when we rely upon the stiffness of the rafters to prevent deformation, to be able to determine the direct stresses in the bars; and for this we will employ an analytical instead of a graphical method, as being the most convenient in this case.

Let us assume that there is no pin at the intersection of the two ties, and that the two rafters are inclined at an angle of  $45^\circ$  to the horizon.

We then have, if  $W$  = the entire load, and  $\alpha$  = angle between  $BK$  and  $KG$ ,

$$ab = ef = \frac{W}{8}, \quad bc = cd = de = \frac{W}{4},$$

$$\tan \alpha = \frac{1}{2}, \quad \sin \alpha = \frac{1}{\sqrt{5}}, \quad \cos \alpha = \frac{2}{\sqrt{5}},$$

Let  $x$  be the stress in each tie, and let  $y = cl = dl$  = thrust in each upper half of the rafters.

Then we must observe that the rafter has, in addition to its direct stresses, a tendency to bend, due to a normal load at the middle, this normal load being equal to the sum of the normal components of  $bc$  and of  $x$ , when these are resolved along and normal to the rafter. Hence

$$\text{normal load} = x \cos \alpha + \frac{W}{4} \sin 45^\circ.$$

This, resolved into components acting at each end of the rafter, gives a normal downward force at each end equal to

$$\frac{1}{2}x \cos \alpha + \frac{1}{8}W \sin 45^\circ.$$

Hence, resolving all the forces acting at the left-hand support into components along and at right angles to the rafter, and imposing the condition of equilibrium that the algebraic sum of their normal components shall equal zero, we have, if we call upward forces positive,

$$\frac{3}{8}W \sin 45^\circ - (\frac{1}{2}x \cos \alpha + \frac{1}{8}W \sin 45^\circ) - x \sin \alpha = 0; \quad (1)$$

but, since

$$x \cos \alpha = 2x \sin \alpha,$$

we have from (1)

$$\begin{aligned} 2x \sin \alpha &= \frac{W}{4} \sin 45^\circ \\ \therefore x \sin \alpha &= \frac{W}{8} \sin 45^\circ \\ \therefore x &= \frac{1}{8} W \frac{\sin 45^\circ}{\sin \alpha}. \end{aligned} \quad (2)$$

Then, proceeding to the apex of the roof, we have that the load

$$cd = \frac{W}{4}$$

gives, when resolved along the two rafters, a stress in each equal to

$$\frac{W}{4} \sin 45^\circ.$$

Hence the load to be supported in a direction normal to the rafter at the apex is

$$\frac{W}{4} \sin 45^\circ + (\frac{1}{2}x \cos \alpha + \frac{W}{8} \sin 45^\circ).$$

Hence, substituting for  $x$  its value, we have

$$y = cl = dl = \frac{W}{2} \sin 45^\circ. \quad (3)$$

Then, proceeding to the left-hand support, and equating to zero the algebraic sum of the components along the rafter, we have

$$\begin{aligned} bk &= (ga - ab) \cos 45^\circ + x \cos \alpha \\ &= \frac{3}{8}W \sin 45^\circ + \frac{1}{4}W \sin 45^\circ = \frac{5}{8}W \sin 45^\circ. \end{aligned} \quad (4)$$

We have thus determined in (2), (3), and (4) the values of  $x$ ,  $y$ , and  $bk = eh$ .

By way of verification, proceed to the middle of the left-hand rafter, and we find the algebraic sum of the components of  $bc$  and  $x$  along the rafter to be

$$\frac{1}{4}W \cos 45^\circ - x \sin \alpha = \frac{1}{8}W \sin 45^\circ;$$

and this is the difference between  $bk$  and  $cl$ , as it should be.

We have thus obtained the direct stresses; and we have, in addition, that the rafter itself is also subjected to a bending-moment from a normal load at the centre, this load being equal to

$$x \cos \alpha + \frac{W}{4} \sin 45^\circ = \frac{W}{2} \sin 45^\circ.$$

How to take this into account will be explained under the "Theory of Beams."

§ 142. Examples. — The following figures of roof-trusses may be considered as a set of examples, for which the stress diagrams are to be worked out.

Observe, that, wherever there is a joint, the truss is to be supposed perfectly flexible, i.e., free to turn around a pin.

## CHAPTER IV.

## BRIDGE-TRUSSES.

§ 143. **Method of Sections.** — It is perfectly possible to determine the stresses in the members of a bridge-truss graphically, or by any methods that are used for roof-trusses.

In this work an analytical method will be used ; i.e., a method of sections. This method involves the use of the analytical conditions of equilibrium for forces in a plane explained in § 63. These are as follows ; viz., —

If a set of forces in a plane, which are in equilibrium, be resolved into components in two directions at right angles to each other, then —

1°. The algebraic sum of the components in one of these directions must be zero.

2°. The algebraic sum of the components in the other of these directions must be zero.

3°. The algebraic sum of the moments of the forces about any axis perpendicular to the plane of the forces must be zero.

Assume, now, a bridge-truss (Figs. 109, 110, 111, 112, pages 176 and 177) loaded at a part or all of the joints. Conceive a vertical section *ab* cutting the horizontal members 6-8 and 7-9 and the diagonal 7-8, and dividing the truss into two parts. Then the forces acting on either part must be in equilibrium, in other words, the external forces, loads, and supporting forces, acting on one part, must be balanced by the stresses in the members cut by the section ; i.e., by the forces exerted by the other part of the truss on the part under consideration. Hence we must have the three following conditions ; viz., —

1°. The algebraic sum of the vertical components of the above-mentioned forces must be zero.

2°. The algebraic sum of the horizontal components of these forces must be zero.

3°. The algebraic sum of the moments of these forces about any axis perpendicular to the plane of the truss must be zero.

§ 144. **Shearing-Force and Bending-Moment.** — Assuming all the loads and supporting forces to be vertical, we shall have the following as definitions.

The *Shearing-Force* at any section is the force with which the part of the girder on one side of the section tends to slide by the part on the other side.

In a girder free at one end, it is equal to the sum of the loads between the section and the free end.

In a girder supported at both ends, it is equal in magnitude to the difference between the supporting force at either end, and the sum of the loads between the section and that supporting force.

The *Bending-Moment* at any section is the resultant moment of the external forces acting on the part of the girder to one side of the section, tending to rotate that part of the girder around a horizontal axis lying in the plane of the section.

In a girder free at one end, it is equal to the sum of the moments of the loads between the section and the free end, about a horizontal axis in the section.

In a girder supported at both ends, it is the difference between the moment of either supporting force, and the sum of the moments of the loads between the section and that support; all the moments being taken about a horizontal axis in the section.

§ 145. **Use of Shearing-Force and Bending-Moment.** — The three conditions stated in § 143 may be expressed as follows:—

1°. The algebraic sum of the horizontal components of the stresses in the members cut by the section must be zero.

2°. The algebraic sum of the vertical components of the stresses in the members cut by the section must balance the shearing-force.

3°. The algebraic sum of the moments of the stresses in the members cut by the section, about any axis perpendicular to the plane of the truss, and lying in the plane of the section, must balance the bending-moment at the section.

As the conditions of equilibrium are three in number, they will enable us to determine the stresses in the members, provided the section does not cut more than three; and this determination will require the solution of three simultaneous equations of the first degree with three unknown quantities (the stresses in the three members).

By a little care, however, in choosing the section, we can very much simplify the operations, and reduce our work to the solution of one equation with only one unknown quantity; the proper choice of the section taking the place of the elimination.

§ 146. **Examples of Bridge-Trusses.** — Figs. 109–112 represent two common kinds of bridge-trusses: in the first two

FIG. 109.

the braces are all diagonal, in the last two they are partly vertical and partly diagonal.

The first two are called Warren girders, or half-lattice girders; since there is only one system of bracing, as in the figures. When, on the other hand, there are more than one system, so that the diagonals cross each other, they are called lattice girders.

§ 147. **General Outline of the Steps to be taken in determining the Stresses in a Bridge-Truss under a Fixed Load.**

1°. If the truss is supported at both ends, find the supporting forces.

FIG. 110.

2°. Assume, in all cases, a section, in such a manner as not to cut more than three members if possible, or, rather, three of those that are brought into action by the loads on the truss; and it will

FIG. 111.

save labor if we assume the section so as to cut two of the three very near their point of intersection.

FIG. 112.

3°. Find the shearing-force at the section.

4°. Find the bending-moment at the section.

5°. Impose the analytical conditions of equilibrium on *all* the forces acting on the part of the girder to one side of the section, — the part between the section and the free end when the girder is free at one end, or either part when it is supported at both ends.

In the cases shown in Figs. 109 and 110, we may describe the process as follows; viz., —

(a) Find the stress in the diagonal from the fact, that (since the stress in the diagonal is the only one that has a vertical component at the section) the vertical component of the stress in the diagonal must balance the shearing-force.

(b) Take moments about the point of intersection of the diagonal and horizontal chord near which the section is taken; then the stresses in those members will have no moment, so that the moment of the stress in the other horizontal must balance the bending-moment at the section. Hence the stress in the horizontal will be found by dividing the bending-moment at the section by the height of the girder.

The above will be best illustrated by some examples.

**EXAMPLE I.** — Given the semi-girder shown in Fig. 110, loaded at joint 13 with 4000 pounds, and at each of the joints 1, 3, 5, 7, 9, and 11 with 8000 pounds. Suppose the length of each chord and each diagonal to be 5 feet. Required the stress in each member.

*Solution.* — For the purpose of explaining the method of procedure, we will suppose that we desire to find first the stresses in 8-10 and 9-10.

Assume a vertical section very near the joint 9, but to the right of it, so that it shall cut both 8-10 and 9-10.

If, now, the truss were actually separated into two parts at this section, the right-hand part would, in consequence of the loads acting on it, separate from the other part. This tendency to separate is counteracted by the following three forces:—

1°. The pull exerted by the part 9- $x$  of the bar 9-11 on the part  $x$ -11 of the same bar.

2°. The thrust exerted by the part 8- $z$  of the bar 8-10 on the part  $z$ -10 of the same bar.

3°. The pull exerted by the part 9- $y$  of the bar 9-10 on the part  $y$ -10 of the same bar.

The shearing-force at this section is

$$8000 + 4000 = 12000 \text{ lbs.},$$

and this is equal to the vertical component of the stress in the diagonal. Hence

$$\text{Stress in 9-10} = \frac{12000}{\sin 60^\circ} = 12000(1.1547) = 13856 \text{ lbs.}$$

This stress is a pull, as may be seen from the fact, that, in order to prevent the part of the girder to the right of the section from sliding downwards under the action of the load, the part 9- $y$  of the diagonal 9-10 must pull the part  $y$ -10 of the same diagonal.

Next take moments about 9: and, since the moment of the stresses in 9-11 and 9-10 about 9 is zero, we must have that the moment of the stress in 8-10; i.e., the product of this stress by the height of the girder, must equal the bending-moment.

The bending-moment about *g* is

$$8000 \times 5 + 4000 \times 10 = 80000 \text{ foot-lbs.}$$

Hence

$$\text{Stress in 8-10} = \frac{80000}{4.33} = 80000(0.23094) = 18475 \text{ lbs.}$$

Proceed in a similar way for all the other members. The work may be arranged as in the following table; the diagonal stresses being deduced from the shearing-forces by multiplying by 1.1547, and the chord stresses from the bending-moments by multiplying by 0.23094.

| Section just to the right of | Shearing-Force in lbs. | Stresses in Diagonals cut by Section, in lbs. |              | Bending-Moment, in foot-lbs. | Stresses in Chords opposite the respective Joints. |              |
|------------------------------|------------------------|---|--------------|------------------------------|--|--------------|
|                              |                        | Tension.                                      | Compression. |                              | Tension.   | Compression. |
| 1                            | 44000                  | 50806   |              | 720000                       |  | 166277       |
| 2                            | 44000                  |   | 50806        | 610000                       | 140873   |              |
| 3                            | 36000                  | 41569   |              | 500000                       |  | 115470       |
| 4                            | 36000                  |   | 41569        | 410000                       | 94685  |              |
| 5                            | 28000                  | 32331   |              | 320000                       |  | 73901        |
| 6                            | 28000                  |   | 32331        | 250000                       | 57735  |              |
| 7                            | 20000                  | 23094   |              | 180000                       |  | 41569        |
| 8                            | 20000                  |   | 23094        | 130000                       | 30022  |              |
| 9                            | 12000                  | 13856   |              | 80000                        |  | 18475        |
| 10                           | 12000                  |   | 13856        | 50000                        | 11547  |              |
| 11                           | 4000                   | 4619  |              | 20000                        |  | 4618         |
| 12                           | 4000                   |   | 4619         | 10000                        | 2309   |              |

EXAMPLE II. — Given the truss (Fig. 109) loaded at each of the lower joints with 10000 lbs. : find the stresses in the members. The length of chord is equal to the length of diagonal = 10 ft.

In future, tensions will be written with the minus, and compressions with the plus sign.

*Solution.* — Total load = 14(10000) = 140000 lbs.

Each supporting force = 70000 "

The entire work is shown in the following tables : —

| Section taken just to the |         | Shearing-Force at Section, in lbs. | Bending-Moment about Joint, in foot-lbs.             |           |
|---------------------------|---------|------------------------------------|--|-----------|
| Right of                  | Left of |                                    |  |           |
| 1                         | 29      | 70000                              | 0  | = 350000  |
| 2                         | 28      | 70000 — 10000 = 60000              | 70000 × 5  | = 650000  |
| 3                         | 27      | 70000 — 10000 = 60000              | 70000 × 10 — 10000 × 5                               | = 950000  |
| 4                         | 26      | 70000 — 20000 = 50000              | 70000 × 15 — 10000 × 10                              | = 1200000 |
| 5                         | 25      | 70000 — 20000 = 50000              | 70000 × 20 — 10000 (5 + 15)                          | = 1450000 |
| 6                         | 24      | 70000 — 30000 = 40000              | 70000 × 25 — 10000 (10 + 20)                         | = 1650000 |
| 7                         | 23      | 70000 — 30000 = 40000              | 70000 × 30 — 10000 (5 + 15 + 25)                     | = 1850000 |
| 8                         | 22      | 70000 — 40000 = 30000              | 70000 × 35 — 10000 (10 + 20 + 30)                    | = 2000000 |
| 9                         | 21      | 70000 — 40000 = 30000              | 70000 × 40 — 10000 (5 + 15 + 25 + 35)                | = 2150000 |
| 10                        | 20      | 70000 — 50000 = 20000              | 70000 × 45 — 10000 (10 + 20 + 30 + 40)               | = 2250000 |
| 11                        | 19      | 70000 — 50000 = 20000              | 70000 × 50 — 10000 (5 + 15 + 25 + 35 + 45)           | = 2350000 |
| 12                        | 18      | 70000 — 60000 = 10000              | 70000 × 55 — 10000 (10 + 20 + 30 + 40 + 50)          | = 2400000 |
| 13                        | 17      | 70000 — 60000 = 10000              | 70000 × 60 — 10000 (5 + 15 + 25 + 35 + 45 + 55)      | = 2450000 |
| 14                        | 16      | 70000 — 70000 = 0                  | 70000 × 65 — 10000 (10 + 20 + 30 + 40 + 50 + 60)     | = 2450000 |
| 15                        | —       | 70000 — 70000 = 0                  | 70000 × 70 — 10000 (5 + 15 + 25 + 35 + 45 + 55 + 65) | = 2450000 |

| 14-16              |       | $-2450000 \times 0.11547 = -282902$ |

EXAMPLE III. — Given the same truss as in Example II., loaded at 2, 4, 6, 8, 10, and 12 with 10000 lbs. at each point, the remaining lower joints being loaded with 50000 lbs. at each joint: find the stresses in the members.

EXAMPLE IV. — Given a semi-girder, free at one end (Fig. 112), loaded at 2, 4, and 6 with 10000 lbs., and at 8, 10, and 12 with 5000 lbs.: find the stresses in the members.

## TRAVELLING-LOAD.

§ 148. **Half-Lattice Girder: Travelling-Load.** — When a girder is used for a bridge, it is not subjected all the time to the same set of loads.

The load in this case consists of two parts, — one, the dead load, including the bridge weight, together with any permanent load that may rest upon the bridge; and the other, the moving or variable load, also called the travelling-load, such as the weight of the whole or part of a railroad train if it is a railroad bridge, or the weight of the passing teams, etc., if it is a common-road bridge. Hence it is necessary that we should be able to determine the amount and distribution of the loads upon the bridge which will produce the greatest tension or the greatest

compression in every member, and the consequent stress produced.

§ 149. **Greatest Stresses in Semi-Girder.** — Wherever the section be assumed in a semi-girder, it is evident that any load placed on the truss at any point between the section and the free end increases both the shearing-force and the bending-moment at that section, and that any load placed between the section and the fixed end has no effect whatever on either the shearing-force or the bending-moment at that section.

Hence every member of a semi-girder will have a greater stress upon it when the entire load is on, than with any partial load.

§ 150. **Greatest Chord Stresses in Girder supported at Both Ends.** — Every load which is placed upon the truss, no matter where it is placed, will produce at any section whatever a *bending-moment* tending to turn the two parts of the truss on the two sides of the section upwards from the supports; i.e., so as to render the truss concave upwards.

Hence every load that is placed upon the truss causes compression in every horizontal upper chord, and tension in every horizontal lower chord. Hence, in order to obtain the greatest chord stresses, we assume the whole of the moving load to be upon the bridge.

§ 151. **Greatest Diagonal Stresses in Girder supported at Both Ends.** — To determine the distribution of the load that will produce the greatest stress of a certain kind (tension or compression) in any given diagonal, let us suppose the diagonal in question to be 7-8 (Fig. 109), through which we take our section *ab*. Now, it is evident that any load placed on the truss between *ab* and the left-hand (nearer) support will cause a shearing-force at that section which will tend to slide the part of the girder to the left of the section downwards with reference to the other part, and hence will cause a compressive stress in 7-8; while any load between the section and the right-

hand (farther) support will cause a shearing-force of the opposite kind, and hence a tension in the bar 7-8.

Now, the bridge weight itself brings an equal load upon each joint; hence, when the bridge weight is the only load upon the truss, the bar 7-8 is in tension.

Hence, any load placed upon the truss between the section and the farther support tends to increase the shearing-force at that section due to the dead load (provided this is equally distributed among the joints); whereas any load placed between the section and the nearer support tends to decrease the shearing-force at the section due to the dead load, or to produce a shearing-force of the opposite kind to that produced by the dead load at that section.

Hence, if we assume the dead load to be equally distributed among the joints, we shall have the two following propositions true:—

(a) In order to determine the greatest stress in any diagonal which is of the same kind as that produced by the dead load, we must assume the moving load to cover all the panel points between the section and the farther abutment, and no other panel points.

(b) In order to determine the greatest stress in any diagonal of the opposite kind to that produced by the dead load, we must assume the moving load to cover all the panel points between the section and the nearer abutment, and no others.

This will be made clear by an example.

EXAMPLE I. — Given the truss shown in Fig. 113. Length of chord = length of diagonal = 10 feet. Dead load = 8000 lbs. applied at each upper panel point. Moving load = 30000 lbs. applied at each upper panel point. Find the greatest stresses in the members.

FIG. 113.

*Solution. (a) Chord Stresses.* — Assume the whole load to be upon the bridge: this will give 38000 lbs. at each upper panel point; i.e., omitting 1 and 17, where the load acts directly on the support, and not on the truss.

FIG. 114.

Hence, considering the bridge so loaded, we shall have the following results for the chord stresses:—

$$\text{Each supporting force} = 38000 \left( \frac{7}{2} \right) = 133000.$$

| Section at |    | Bending-Moment, in foot-lbs.             |             |
|------------|----|--|-------------|
| 2          | 16 | $133000 \times 5$                        | $= 665000$  |
| 3          | 15 | $133000 \times 10$                       | $= 1330000$ |
| 4          | 14 | $133000 \times 15 - 38000 \times 5$      | $= 1805000$ |
| 5          | 13 | $133000 \times 20 - 38000 \times 10$     | $= 2280000$ |
| 6          | 12 | $133000 \times 25 - 38000(5 + 15)$       | $= 2565000$ |
| 7          | 11 | $133000 \times 30 - 38000(10 + 20)$      | $= 2850000$ |
| 8          | 10 | $133000 \times 35 - 38000(5 + 15 + 25)$  | $= 2945000$ |
| 9          |    | $133000 \times 40 - 38000(10 + 20 + 30)$ | $= 3040000$ |

| Numbers of Chords. |       | Stresses in Upper Chords.           |
|--------------------|-------|-------------------------------------|
| 1-3                | 15-17 | $665000 \times 0.11547 = + 76788$   |
| 3-5                | 13-15 | $1805000 \times 0.11547 = + 208423$ |
| 5-7                | 11-13 | $2565000 \times 0.11547 = + 296181$ |
| 7-9                | 9-11  | $2945000 \times 0.11547 = + 340059$ |

| Numbers of Chords. |       | Stresses in Lower Chords.           |
|--------------------|-------|-------------------------------------|
| 2-4                | 14-16 | $-1330000 \times 0.11547 = -153575$ |
| 4-6                | 12-14 | $-2280000 \times 0.11547 = -263272$ |
| 6-8                | 10-12 | $-2850000 \times 0.11547 = -329090$ |
| 8-10               |       | $-3040000 \times 0.11547 = -351029$ |

Next, as to the diagonals, take, for instance, the diagonal 7-8. When the dead load alone is on the bridge, the diagonal 7-8 is in tension. From the preceding, we see that the greatest tension is produced in this bar when the moving load is on the points 9, 11, 13, and 15, and the dead load only on the points 3, 5, 7. Now, a load of 38000 lbs. at 13, for instance, causes a shearing-force of  $\frac{4}{16}(38000) = 9500$  lbs. at any section to the left of 13; and this shearing-force tends to cause the part to the left of the section to slide upwards, and that to the right downwards.

On the other hand, with the same load at the same place, there is produced a shearing-force of  $\frac{12}{16}(38000) = 28500$  lbs. at any section to the right of 13; and this shearing-force tends to cause the part to the left to slide downwards, and that to the right upwards. Paying attention to this fact, we shall have, when the loads are distributed as above described, a shearing-force at the bar 7-8 causing tension in this bar; the magnitude of this shearing-force being

$$\frac{38000}{16}(2 + 4 + 6 + 8) - \frac{8000}{16}(2 + 4 + 6) = 41500.$$

Hence, we may arrange the work as follows :—

| Numbers of Diagonals. |       | Greatest Shearing-Forces producing Stresses of Same Kind as Dead Load. | Greatest Stresses in Diagonals of Same Kind as those due to Dead Load. |
|-----------------------|-------|--|--|
| 1-2                   | 17-16 | $\frac{38000}{16}(2+4+6+8+10+12+14) = 133000$                          | -153575  |
| 2-3                   | 16-15 | $\frac{38000}{16}(2+4+6+8+10+12+14) = 133000$                          | +153575  |
| 3-4                   | 15-14 | $\frac{38000}{16}(2+4+6+8+10+12) - \frac{8000}{16}(2) = 98750$         | -114027  |
| 4-5                   | 14-13 | $\frac{38000}{16}(2+4+6+8+10+12) - \frac{8000}{16}(2) = 98750$         | +114027  |
| 5-6                   | 13-12 | $\frac{38000}{16}(2+4+6+8+10) - \frac{8000}{16}(2+4) = 68250$          | -78808   |
| 6-7                   | 12-11 | $\frac{38000}{16}(2+4+6+8+10) - \frac{8000}{16}(2+4) = 68250$          | +78808   |
| 7-8                   | 11-10 | $\frac{38000}{16}(2+4+6+8) - \frac{8000}{16}(2+4+6) = 41500$           | -47920   |
| 8-9                   | 10-9  | $\frac{38000}{16}(2+4+6+8) - \frac{8000}{16}(2+4+6) = 41500$           | +47920   |

| Numbers of Diagonals. |       | Greatest Shearing-Forces producing Stresses of Kind Opposite from Dead Load. | Greatest Stresses in Diagonals of Kind Opposite from Dead Load. |
|-----------------------|-------|--|---|
| 8-9                   | 10-9  | $\frac{38000}{16}(2+4+6) - \frac{8000}{16}(2+4+6+8) = 18500$                 | -21362  |
| 7-8                   | 11-10 | $\frac{38000}{16}(2+4) - \frac{8000}{16}(2+4+6+8+10) = -750$                 | None.   |

Hence, the diagonals 8-9 and 9-10 are the only ones that, under any circumstances, can have a stress of the kind opposite to that to which they are subjected under the dead load alone.

Fig. 114 exhibits the manner of writing the stresses on the diagram.

§ 152. **General Application of this Method.** — It is plain that the method used above will apply to any single system of bridge-truss with horizontal chords and diagonal bracing, whatever be the inclination of the braces.

When seeking the stress in a diagonal, the section must be so taken as to cut that diagonal; and, as far as this stress alone is concerned, it may be equally well taken at any point, as well as near a joint, provided only it cuts that diagonal which is in action under the load that produces the greatest stress in this one, and no other.

On the other hand, when we seek the stress in a horizontal chord, the section might very properly be taken through the joint opposite that chord.

Taking it very near the joint, only serves to make one section answer both purposes simultaneously.

§ 153. **Bridge-Trusses with Vertical and Diagonal Bracing.** — When, as in Figs. 111 and 112, there are both vertical and diagonal braces, and also horizontal chords, we may determine the stresses in the diagonals and in the chords just as before; only we must take the section just to one side of a joint, and never through the joint.

As to the verticals, in order to determine the stress in any vertical, we must impose the conditions of equilibrium between the vertical components of the forces acting at one end of that vertical: thus, if the loads are at the upper joints in Fig. 111, then the stress in vertical 3-2 must be equal and opposite to the vertical component of the stress in diagonal 1-2, as these stresses are the only vertical forces acting at joint 2.

Vertical 5-4 has for its stress the vertical component of the stress in 3-4, etc. Thus

Stress in 3-2 = shearing-force in panel 1-3,

Stress in 5-4 = shearing-force in panel 3-5, etc.

On the other hand, if the loads be applied at the lower joints, then

Stress in 3-2 = shearing-force in panel 3-5,

Stress in 5-4 = shearing-force in panel 5-7, etc.

EXAMPLE. — Given the truss shown in Fig. III. Given panel length = height of truss = 10 feet, dead load per panel point = 12000 lbs., moving load per panel point = 23000 lbs.; load applied at upper joints.

Solution. (a) *Chord Stresses*. — Assume the entire load on the bridge, i.e., 35000 lbs. per panel point. Hence

Total load on truss = 13 (35000) = 455000 lbs.,

Each supporting force = 227500 lbs.

| Joint near which Section is taken. |    | Bending-Moment at the Section very near the Joint, on Either Side of the Joint. |           |
|------------------------------------|----|---|-----------|
| 1                                  | 28 | 0   |           |
| 3                                  | 27 | $227500 \times 10$  | = 2275000 |
| 5                                  | 25 | $227500 \times 20 - 35000 \times 10$  | = 4200000 |
| 7                                  | 23 | $227500 \times 30 - 35000(10 + 20)$   | = 5775000 |
| 9                                  | 21 | $227500 \times 40 - 35000(10 + 20 + 30)$  | = 7000000 |
| 11                                 | 19 | $227500 \times 50 - 35000(10 + 20 + 30 + 40)$                                   | = 7875000 |
| 13                                 | 17 | $227500 \times 60 - 35000(10 + 20 + 30 + 40 + 50)$                              | = 8400000 |
| 15                                 | —  | $227500 \times 70 - 35000(10 + 20 + 30 + 40 + 50 + 60)$                         | = 8575000 |

To find any chord stress, divide the bending-moment at a section cutting the chord, and passing close to the opposite joint, by the height of the girder, which in this case is 10. Hence we have for the chord stresses (denoting, as before, compression by +, and tension by —):—

| Stresses in Upper Chords. |       |         | Stresses in Lower Chords. |       |         |
|---------------------------|-------|---------|---------------------------|-------|---------|
| 1- 3                      | 27-28 | +227500 | 2- 4                      | 24-26 | -227500 |
| 3- 5                      | 25-27 | +420000 | 4- 6                      | 22-24 | -420000 |
| 5- 7                      | 23-25 | +577500 | 6- 8                      | 20-22 | -577500 |
| 7- 9                      | 21-23 | +700000 | 8-10                      | 18-20 | -700000 |
| 9-11                      | 19-21 | +787500 | 10-12                     | 16-18 | -787500 |
| 11-13                     | 17-19 | +840000 | 12-14                     | 14-16 | -840000 |
| 13-15                     | 15-17 | +857500 |                           |       |         |

**Diagonals.** — It is evident, that, for the diagonals, the same rule holds as in the case of the Warren girder: i.e., the greatest stress of the same kind as that produced by the dead load occurs when the moving load is on all the joints between the diagonal in question and the farther abutment; whereas the greatest stress of the opposite kind occurs when the moving load covers all the joints between the diagonal in question and the nearer abutment.

The work of determining the greatest shearing-forces may be arranged as in tables on p. 191.

**Counterbraces.** — If the truss were constructed with those diagonals only that slope downwards towards the centre, and which may be called the main braces, the diagonals 11-12, 13-14, 14-17, and 16-19 would sometimes be called upon to bear a thrust, and the verticals 12-13 and 17-16 a pull: this would necessitate making these diagonals sufficiently strong to resist the greatest thrust to which they are liable, and fixing the verticals in such a way as to enable them to bear a pull.

In order to avoid this, the diagonals 10-13, 12-15, 15-16, and 17-18 are inserted, which are called counterbraces, and which come into action only when the corresponding main

braces would otherwise be subjected to thrust. They also prevent any tension in the verticals.

| Diagonals. |       | Greatest Shearing-Forces of the Same Kind as those produced by Dead Load. |            |
|------------|-------|---|------------|
| 1-2        | 28-26 | $\frac{35000}{14}(1+2+3+\dots+13)$  | $= 227500$ |
| 3-4        | 27-24 | $\frac{35000}{14}(1+2+3+\dots+12) - \frac{12000}{14}(1)$                  | $= 194143$ |
| 5-6        | 25-22 | $\frac{35000}{14}(1+2+3+\dots+11) - \frac{12000}{14}(1+2)$                | $= 162429$ |
| 7-8        | 23-20 | $\frac{35000}{14}(1+2+3+\dots+10) - \frac{12000}{14}(1+2+3)$              | $= 132357$ |
| 9-10       | 21-18 | $\frac{35000}{14}(1+2+3+\dots+9) - \frac{12000}{14}(1+2+\dots+4)$         | $= 103929$ |
| 11-12      | 19-16 | $\frac{35000}{14}(1+2+3+\dots+8) - \frac{12000}{14}(1+2+\dots+5)$         | $= 77143$  |
| 13-14      | 17-14 | $\frac{35000}{14}(1+2+3+\dots+7) - \frac{12000}{14}(1+2+\dots+6)$         | $= 52000$  |

| Diagonals. |       | Greatest Shearing-Forces of the Opposite Kind to those produced by Dead Load. |            |
|------------|-------|---|------------|
| 13-14      | 17-14 | $\frac{35000}{14}(1+2+3+\dots+6) - \frac{12000}{14}(1+2+\dots+7)$             | $= 28500$  |
| 11-12      | 19-16 | $\frac{35000}{14}(1+2+\dots+5) - \frac{12000}{14}(1+2+\dots+8)$               | $= 6643$   |
| 9-10       | 21-18 | $\frac{35000}{14}(1+2+\dots+4) - \frac{12000}{14}(1+2+\dots+9)$               | $= -13571$ |

The main braces and counterbraces of a panel are never in action simultaneously. Hence we have, for the greatest stresses in the diagonals, the following results, obtained by multiplying the corresponding shearing-forces by  $\frac{1}{\cos 45^\circ} = 1.414$ .

In the following I have used this number to three decimal places, as being sufficiently accurate for practical purposes.

| Stresses in Main Braces. |       |         | Stresses in Counterbraces. |       |        |
|--------------------------|-------|---------|----------------------------|-------|--------|
| 1- 2                     | 28-26 | -321685 | 15-12                      | 15-16 | -40299 |
| 3- 4                     | 27-24 | -274518 | 13-10                      | 17-18 | - 9393 |
| 5- 6                     | 25-22 | -229675 |                            |       |        |
| 7- 8                     | 23-20 | -187153 |                            |       |        |
| 9-10                     | 21-18 | -146956 |                            |       |        |
| 11-12                    | 19-16 | -109080 |                            |       |        |
| 13-14                    | 17-14 | - 73528 |                            |       |        |

**Vertical Posts.** — Since the loads are applied at the upper joints, the conditions of equilibrium at the lower joints require that the thrust in any vertical post shall be equal to the vertical component of the tension in that diagonal which, being in action at the time, meets it at its lower end.

Hence it is equal to the shearing-force in that panel where the acting diagonal meets it at its lower end.

The post 15-14 is a counterbrace, and comes into action only when the diagonal counterbraces are in action.

We therefore have, for the posts, the following as the greatest thrusts :—

STRESSES IN VERTICALS.

|       |       |          |
|-------|-------|----------|
| 3- 2  | 27-26 | +227500  |
| 5- 4  | 25-24 | +194143  |
| 7- 6  | 23-22 | +162429  |
| 9- 8  | 21-20 | +132357  |
| 11-10 | 19-18 | +103929  |
| 13-12 | 17-16 | + 77143. |
| 15-14 |       | + 28500  |

Fig. 115 shows the stresses marked on the diagram.

§ 154. Manner of Concentrating the Load at the Joints.

— In using the methods given above, we are assuming that all the loads are concentrated at the joints, and that none are distributed over any of the pieces. As far as the moving load is concerned, and also all of the dead load except the weight of the truss itself, this always is, or ought to be, effected; and it is accomplished in a manner similar to that adopted in the case of roof-trusses. This method is shown in the figure (Fig. 116); floor-beams being laid across from

FIG. 116.

girder to girder at the joints, on top of which are laid longitudinal beams, and on these the sleepers if it is a railroad bridge, or the floor if it is a road bridge. The weight of the *truss* itself is so small a part of what the bridge is called upon to bear, that it can, without appreciable error, be considered as concentrated at the joints either of the upper chord, of the lower chord, or of both, according to the manner in which the rest of the load is distributed.

§ 155. Closer Approximation to Actual Shearing-Force. — In our computations of greatest shearing-force, we

FIG. 115.

make an approximation which is generally considered to be

sufficiently close, and which is always on the safe side. To illustrate it, take the case of panel 3-5 of the last example. In determining its greatest shearing-force, we considered a load of 35000 lbs. per panel point to rest on all the joints from the right-hand support to joint 5, inclusive, and the dead load to rest on all the other joints of the truss. Now, it is impossible, if the load is distributed uniformly on the floor of the bridge, to have a load of 35000 lbs. on 5 and 12000 on 3 simultaneously; for, if the moving load extended on the bridge floor only up to 5, the load on 5 would be only  $12000 + \frac{1}{2}(23000) = 23500$  lbs., and that on 3 would then be 12000 lbs. If, on the other hand, the moving load extends beyond 5 at all, as it must if the load on 5 is to be greater than 23500 lbs., then part of it will rest on 3, and the load on 3 will then be greater than 12000 lbs.; for whatever load there is between 3 and 5 is supported at 3 and 5.

Moreover, we know that the effect of increasing the load on 5 is to increase the shearing-force, provided we do not at the same time increase that on 3 so much as to destroy the effect of increasing that on 5.

Hence, there must be some point between 3 and 5 to which the moving load must extend in order to render the shearing-force in panel 3-5 a maximum.

Let the distance of this point from 5 be  $x$ ; then, if we let  $w = \frac{23000}{10}$  = moving load per foot of length,

$$\text{Moving load on panel} = wx,$$

$$\text{Part supported at 3} = \frac{wx^2}{20},$$

$$\text{Part supported at 5} = wx - \frac{wx^2}{20}.$$

Hence, portion of shearing-force due to the moving load on panel 3-5 equals

$$\frac{12}{14} \left( wx - \frac{wx^2}{20} \right) - \frac{1}{14} \frac{wx^2}{20} = \frac{w}{14} \left( 12x - \frac{13x^2}{20} \right).$$

This becomes a maximum when its first differential co-efficient becomes zero, i.e., when

$$12 - \frac{13}{10}x = 0;$$

therefore

$$x = 9.23.$$

Hence, when the moving load extends to a distance of 9.23 feet from 5, then the shearing-force in panel 3-5, and hence the stress in diagonal 3-4, is a maximum.

| Diagonals in Panel where Shearing-Force is taken. |       | Portion of Shearing-Force due to Moving Load on Panel. | Value of $x$ , in feet. | Portion of Load at Joints named below. |       | Portion of Load at Joints named below. |       |
|---|-------|--|-------------------------|--|-------|--|-------|
| 1-3   | 27-28 | $\frac{w}{14} \left( 13x - \frac{13x^2}{20} \right)$   | 10.00                   | 1                                      | 11500 | 3                                      | 11500 |
| 3-5   | 25-27 | $\frac{w}{14} \left( 12x - \frac{13x^2}{20} \right)$   | 9.23                    | 3                                      | 9797  | 5                                      | 11432 |
| 5-7   | 23-25 | $\frac{w}{14} \left( 11x - \frac{13x^2}{20} \right)$   | 8.46                    | 5                                      | 8230  | 7                                      | 11227 |
| 7-9   | 21-23 | $\frac{w}{14} \left( 10x - \frac{13x^2}{20} \right)$   | 7.69                    | 7                                      | 6801  | 9                                      | 10886 |
| 9-11  | 19-21 | $\frac{w}{14} \left( 9x - \frac{13x^2}{20} \right)$    | 6.92                    | 9                                      | 5507  | 11                                     | 10409 |
| 11-13   | 17-19 | $\frac{w}{14} \left( 8x - \frac{13x^2}{20} \right)$    | 6.15                    | 11                                     | 4350  | 13                                     | 9795  |
| 13-15   | 15-17 | $\frac{w}{14} \left( 7x - \frac{13x^2}{20} \right)$    | 5.38                    | 13                                     | 3329  | 15                                     | 9045  |

To show how the adoption of this method would affect the resulting stresses in the diagonals and verticals, I have given the work above, and shown the difference between these and

the former results. In this table  $x$  = distance covered by load from end of panel nearest the centre.

| Panels. |       | Greatest Shearing-Force of Same Kind as that due to Dead Load.  |          |
|---------|-------|---|----------|
| 1-3     | 27-28 | $\frac{35000}{14}(1+\dots+13)$  | = 227500 |
| 3-5     | 25-27 | $\frac{35000}{14}(1+\dots+11) + \frac{12}{14}(23432) - \frac{x}{14}(21797)$                             | = 183528 |
| 5-7     | 23-25 | $\frac{35000}{14}(1+\dots+10) + \frac{11}{14}(23227) - \frac{9}{14}(20230) - \frac{x}{14}(12000)$       | = 152003 |
| 7-9     | 21-23 | $\frac{35000}{14}(1+\dots+9) + \frac{10}{14}(22886) - \frac{3}{14}(18801) - \frac{12000}{14}(1+2)$      | = 122247 |
| 9-11    | 19-21 | $\frac{35000}{14}(1+\dots+8) + \frac{9}{14}(22409) - \frac{4}{14}(17507) - \frac{12000}{14}(1+2+3)$     | = 94261  |
| 11-13   | 17-19 | $\frac{35000}{14}(1+\dots+7) + \frac{8}{14}(21795) - \frac{5}{14}(16350) - \frac{12000}{14}(1+\dots+4)$ | = 68043  |
| 13-15   | 15-17 | $\frac{35000}{14}(1+\dots+6) + \frac{7}{14}(21664) - \frac{6}{14}(14710) + \frac{12000}{14}(1+\dots+5)$ | = 44171  |

Hence, for stresses in main braces, we have

| Diagonals. |       | Stresses. |
|------------|-------|-----------|
| 1-2        | 28-26 | -321685   |
| 3-4        | 27-24 | -259509   |
| 5-6        | 25-22 | -214932   |
| 7-8        | 23-20 | -172857   |
| 9-10       | 21-18 | -133285   |
| 11-12      | 19-16 | -96213    |
| 13-14      | 17-14 | -62458    |

Moreover, for the shearing-forces of opposite kind from

those due to dead load, we have, if  $x$  = distance from end of panel nearest support which is covered by moving load, —

| Panels. |       | Portion of Shear due to Moving Load on Panel.       | Value of $x$ . | Portion of Load at Joints named below. |      | Portion of Load at Joints named below. |      |
|---------|-------|---|----------------|--|------|--|------|
| 13-15   | 17-15 | $\frac{w}{14} \left( 6x - \frac{13x^2}{20} \right)$ | 4.62           | 15                                     | 2455 | 13                                     | 8171 |
| 11-13   | 19-17 | $\frac{w}{14} \left( 5x - \frac{13x^2}{20} \right)$ | 3.84           | 13                                     | 1695 | 11                                     | 7137 |

| Panels. |       | Greatest Shearing-Forces of Opposite Kind from those due to Dead Load.  |
|---------|-------|---|
| 13-15   | 17-15 | $\frac{35000}{14}(1+\dots+5) + \frac{6}{14}(20171) - \frac{7}{14}(14455) - \frac{12000}{14}(1+\dots+6) = 20917$ |
| 11-13   | 19-17 | $\frac{35000}{14}(1+\dots+4) + \frac{5}{14}(19137) - \frac{6}{14}(13695) - \frac{12000}{14}(1+\dots+7) = 1965$  |

Hence we have the following as the stresses in the counter-braces :—

| Counter-Braces. |       | Stresses. |
|-----------------|-------|-----------|
| 15-12           | 15-16 | — 29577   |
| 13-10           | 17-18 | — 2778    |

And, for the verticals, we have the new, instead of the old, shearing-forces.

The following table compares the results :—

| Diagonals. |       | Stress, Ordinary Method. | Stress, New Method. | Difference. |
|------------|-------|--------------------------|---------------------|-------------|
| 1- 2       | 28-26 | -321685                  | -321685             |             |
| 3- 4       | 27-24 | -274518                  | -259509             | 15009       |
| 5- 6       | 25-22 | -229675                  | -214932             | 14743       |
| 7- 8       | 23-20 | -187153                  | -172857             | 14296       |
| 9-10       | 21-18 | -146596                  | -133285             | 13671       |
| 11-12      | 19-16 | -109080                  | - 96213             | 12867       |
| 13-14      | 17-14 | - 73528                  | - 62458             | 11070       |
| 15-12      | 15-16 | - 40299                  | - 29577             | 10722       |
| 13-10      | 17-18 | - 9393                   | - 2783              | 7610        |

| Verticals. |       | Stress, Ordinary Method. | Stress, New Method. | Difference. |
|------------|-------|--------------------------|---------------------|-------------|
| 3- 2       | 27-26 | +227500                  | +227500             | 10615       |
| 5- 4       | 25-24 | +194143                  | +183528             | 10426       |
| 7- 6       | 23-22 | +162429                  | +152003             | 10110       |
| 9- 8       | 21-20 | +132357                  | +122247             | 9668        |

| 15-14      |       | + 28500                  | + 20917             |             |

§ 156. **Compound Bridge-Trusses.**—The trusses already discussed have contained but a single system of latticing, or

at least only one system that comes in play at one time; so that a vertical section never cuts more than three bars that are in action simultaneously, the main brace having no stress upon it when the counterbrace is in action, and *vice versa*.

We may, however, have bridge-trusses with more than one system of lattices; and, in determining the stresses in their members, we must resolve them into their component systems, and determine the greatest stress in each system separately, and then, for bars which are common to the two systems, add together the stresses brought about by each.

In some cases, the design is such that it is possible to resolve the truss into systems in more than one way, and then there arises an uncertainty as to which course the stresses will actually pursue.

In such cases, the only safe way is to determine the greatest stress in each piece with every possible mode of resolution of the systems, and then to design each piece in such a way as to be able to resist that stress.

Generally, however, such ambiguity is an indication of a waste of material; as it is most economical to put in the bridge only those pieces that are absolutely necessary to bear the stresses, as other pieces only add so much weight to the structure, and are useless to bear the load.

The mode of proceeding can be best explained by some examples.

**EXAMPLE I.**—Given the lattice-girder shown in Fig. 117, loaded at the lower panel points only. Dead load = 7200 lbs. per panel point, moving load = 18000 lbs per panel point; let the entire length of bridge be 60 feet; let the angle made by braces with horizontal =  $60^{\circ}$ .

FIG. 117.

*This truss evidently consists of the two single trusses shown in Figs. 117a*

*and 117b; and we can compute the greatest stress of each*

*kind in each member of these trusses, and thus obtain at once all the diagonal stresses, and then, by addition, the greatest chord stresses.*

FIG. 117a.

FIG. 117b.

Thus the stress in 1-3 (Fig. 117) is the same as the stress in 1-5 (Fig. 117a).

The stress in 3-5 = stress in 1-5 (Fig. 117a) + stress in 3-7 (Fig. 117b).

The stress in 5-7 = stress in 5-9 (Fig. 117a) + stress in 3-7 (Fig. 117b).

The results are given on the diagram (Fig. 117c); the work being left for the student, as it is similar to that done heretofore.

FIG. 117c.

EXAMPLE II. — Given the lattice-girder shown in Fig. 118. Given, as before, Dead load = 7200 lbs. per panel point, moving load = 18000 lbs. per panel point, entire length of bridge = 25 feet; load applied at lower panel points.

*Solution.* — In this case, there are two possible modes of resolving it into systems. The first is shown in Figs. 118a and 118b: and this is necessarily the mode of division that must hold whenever the load is unevenly distributed, or when the

travelling-load covers only a part of the bridge; for a single load at 6 is necessarily put in communication with the support at 2 by means of the diagonals 6-3 and 3-2, and with the support at 3 by means of the diagonals 6-7, 7-10, 10-11, and the vertical 11-12, and can cause no stress in the other diagonals.

FIG. 118.

FIG. 118a.

FIG. 118b.

FIG. 118c.

FIG. 118d.

When, however, the whole travelling-load is on the bridge, it is perfectly possible to divide it into the two trusses shown in Figs. 118c and 118d, the diagonals 4-5, 7-10, 6-7, and 5-8 having no stress upon them.

When the load is unevenly distributed, we have certainly the first method of division; and when evenly, we are not sure which will hold.

Hence we must compute the greatest stresses with each mode of division, and use for each member the greatest; for thus only shall we be sure that the truss is made strong enough.

We shall thus have the following results:—

FIRST MODE OF DIVISION (FIGS. 118*a* AND 118*b*).

| Diagonals.             |                        | Greatest Shearing-Force<br>of One Kind. | Greatest Shearing-Force<br>of Opposite Kind. | Corresponding Stresses. |        |
|------------------------|------------------------|---|--|-------------------------|--------|

## SECOND METHOD OF DIVISION (FIGS. 118c AND 118d).

*Diagonals* (Fig. 118c).

| Diagonals. |       | Maximum Shear. | Corresponding Stresses. |
|------------|-------|----------------|-------------------------|
| 1-4        | 10-11 | 25200          | -29098                  |
| 4-5        | 7-10  | 0              | 0                       |

Fig. 118d.

| Diagonals. |      | Maximum Shear. | Corresponding Stresses. |
|------------|------|----------------|-------------------------|
| 2-3        | 9-12 | 25200          | +29098                  |
| 3-6        | 8-9  | 25200          | -29098                  |
| 6-7        | 5-8  | 0              | 0                       |

*Chords.*

Each supporting force in either figure = 25200.

Fig. 118c.

Bending-moment anywhere between 4 and 10 =  $(25200)(5) = 126000$ ;

$\therefore$  Stress in 1-11 = +14549,

$\therefore$  Stress in 4-10 = -14549.

Fig. 118d.

Bending-moment at 3 or 9 = 126000,

Bending-moment anywhere between 6 and 8 = 252000;

$\therefore$  Stress in 3-9 = +29098,

Stress in 2-6 or 8-12 = -14549,

Stress in 6-8 = -29098.

Hence we have for chord stresses, with this second division, —

| Chords. |       |            | Stresses. |
|---------|-------|------------|-----------|
| 1-3     | 9-11  | 1-11 + 0   | +14549    |
| 3-5     | 7- 9  | 1-11 + 3-9 | +43647    |
| 5-7     | -     | 1-11 + 3-9 | +43647    |
| 2-4     | 10-12 | 0 + 2-6    | -14549    |
| 4-6     | 8-10  | 4-10 + 2-6 | -29098    |
| 6-8     | -     | 4-10 + 6-8 | -43647    |

Hence, selecting for each bar the greatest, we shall have, as the stresses which the truss must be able to resist, —

|     |       |        |        |     |       |        |
|-----|-------|--------|--------|-----|-------|--------|
| 1-4 | 10-11 | + 0    | -34918 | 1-3 | 9-11  | +17459 |
| 2-3 | 12- 9 | +29098 | - 0    | 3-5 | 7- 9  | +43647 |
| 3-6 | 9- 8  | + 0    | -29098 | 5-7 | -     | +46558 |
| 4-5 | 10- 7 | +11639 | - 5820 | 2-4 | 10-12 | -14549 |
| 5-8 | 7- 6  | + 5820 | -11639 | 4-6 | 8-10  | -46557 |
|     |       |        |        | 6-8 |       | -69836 |

These results are recorded in Fig. 118e.

FIG. 118e.

§ 157. Other Trusses. — In Figs. 119, 120, and 121, we have examples of the double-panel system with the load placed

at the lower panel points only. When, as in 119 and 120, the number of panels is odd, the same ambiguity arises as took place in Fig. 118. When, on the other hand, the number of panels is even, as shown in Fig. 121, there is only one mode of division into systems possible. The diagrams speak for themselves, and need no explanation.

FIG. 119.

FIG. 119a.

FIG. 119b.

FIG. 119c.

FIG. 119d.

FIG. 1200.

FIG. 1201.

FIG. 1202.

FIG. 1203.

FIG. 1204.

FIG. 1205.

FIG. 121a.

FIG. 121b.

FIG. 122.

The trusses given above may be considered as examples, to be solved by the student by assuming the dead and the moving load per panel point respectively.

§ 158. **Fink's Truss.** — The description of this truss will be evident from the figure. There is, first, the primary truss 1-8-16; then on each side of 9-8 (the middle post of this truss) is a secondary truss (1-4-9 on the left, and 9-12-16 on the right).

FIG. 123.

Each of these secondary trusses contains a pair of smaller secondary trusses, and the division might be continued if the segments into which the upper chord is thus divided were too long.

Of the inclined ties, there is none in which any load tends to produce compression; in other words, every load either increases the tension in the tie, or else does not affect it. Hence

the greatest stresses in all the members will be attained when the entire travelling-load is on the truss, and we need only consider that case.

The determination of the stress in any one member can readily be obtained by determining, by means of the triangle of forces, the stress in that member due to the presence of the total load per panel point, at each point, and then adding the results. This will be illustrated by a few diagonals.

Let angle 8-1-9 =  $i$ ,

Let angle 4-1-5 =  $i_1$ ,

Let angle 2-1-3 =  $i_2$ ;

we shall have, if  $w + w_1$  = entire load per panel point, —

| Designation of Ties. | EFFECT OF LOADS AT           |                              |                              |                            |                            |                            |                            | Resultant Tensions.           |
|----------------------|------------------------------|------------------------------|------------------------------|----------------------------|----------------------------|----------------------------|----------------------------|-------------------------------|
|                      | 8                            | 5                            | 7                            | 9                          | 11                         | 13                         | 15                         |                               |
| 1-2                  | $\frac{w + w_1}{2 \sin i_2}$ | 0                            | 0                            | 0                          | 0                          | 0                          | 0                          | $\frac{w + w_1}{2 \sin i_2}$  |
| 2-5                  | $\frac{w + w_1}{2 \sin i_2}$ | 0                            | 0                            | 0                          | 0                          | 0                          | 0                          | $\frac{w + w_1}{2 \sin i_2}$  |
| 5-6                  | 0                            | 0                            | $\frac{w + w_1}{2 \sin i_2}$ | 0                          | 0                          | 0                          | 0                          | $\frac{w + w_1}{2 \sin i_2}$  |
| 6-9                  | 0                            | 0                            | $\frac{w + w_1}{2 \sin i_2}$ | 0                          | 0                          | 0                          | 0                          | $\frac{w + w_1}{2 \sin i_2}$  |
| 1-4                  | $\frac{w + w_1}{4 \sin i_1}$ | $\frac{w + w_1}{2 \sin i_1}$ | $\frac{w + w_1}{4 \sin i_1}$ | 0                          | 0                          | 0                          | 0                          | $\frac{w + w_1}{\sin i_1}$    |
| 4-9                  | $\frac{w + w_1}{4 \sin i_1}$ | $\frac{w + w_1}{2 \sin i_1}$ | $\frac{w + w_1}{4 \sin i_1}$ | 0                          | 0                          | 0                          | 0                          | $\frac{w + w_1}{\sin i_1}$    |
| 1-8                  | $\frac{w + w_1}{8 \sin i}$   | $\frac{w + w_1}{4 \sin i}$   | $\frac{w + w_1}{8 \sin i}$   | $\frac{w + w_1}{2 \sin i}$ | $\frac{w + w_1}{8 \sin i}$ | $\frac{w + w_1}{4 \sin i}$ | $\frac{w + w_1}{8 \sin i}$ | $\frac{3(w + w_1)}{2 \sin i}$ |

The stresses in all the other members may be found in a similar manner.

§ 159. **Bollman's Truss.** — The description of this truss is made sufficiently clear by the figure. The upper chord is made in separate pieces; and the short diagonals 2-5, 3-4, 4-7, 5-6, 7-8, 6-9, 8-11, and 9-10 are only needed to prevent a bending of the upper chord at the joints.

FIG. 124.

When this is their only object, the stress upon them cannot be calculated: indeed, it is zero until bending takes place; and then it is the less, the less the bending. Hence, in this case, the stress is wholly taken up by the principal ties; and these have their greatest stress when the whole load is on the bridge.

The computation of the stresses is made in a similar manner to that used in the Fink.

§ 160. **General Remarks.** — The methods already explained are intended to enable the student to solve any case of a bridge-truss where there is no ambiguity as to the course pursued by the stresses.

In cases where a large number of trusses of one given type are to be computed, it would, as a rule, be a saving of labor to determine formulæ for the stresses in the members, and then substitute in these formulæ.

Such formulæ may be deduced by using letters to denote the load and dimensions, instead of inserting directly their numerical values; and then, having deduced the formulæ for the type of truss, we can apply it to any case by merely substituting for the letters their numerical values corresponding to that case.

Such sets of formulæ would apply merely to specific styles of trusses, and any variation in these styles would require the formulæ to be changed.

In order to show how such formulæ are deduced, a few will be deduced for such a bridge as is shown in Fig. 111.

Let the load be applied at the upper panel points only; let dead load per panel point =  $w$ , moving load per panel point =  $w_1$ . Let the whole number of panels be  $N$ ,  $N$  being an even number. Let the length of one panel = height of truss =  $l$ . Then length of entire span =  $Nl$ .

Consider the  $n^{\text{th}}$  panel from the middle.

The stress in the main tie is greatest when the moving load is on all the panel points from the farther abutment up to the panel in question.

Hence, for the  $n^{\text{th}}$  panel from the middle, the greatest shearing-force that causes tension in the main tie

$$\begin{aligned} &= \frac{w+w_1}{N} \left\{ 1+2+3+\dots+\frac{N}{2}+n \right\} - \frac{w}{N} \left\{ 1+2+3+\dots+\frac{N}{2}-n-1 \right\} \\ &= \frac{1}{2N} \left\{ w_1 \left[ \left( \frac{N}{2} + n \right)^2 + \frac{N}{2} + n \right] + \frac{w}{2} (2n+1)N \right\}. \end{aligned}$$

Hence stress in main tie

$$= \frac{\sqrt{2}}{2N} \left\{ w_1 \left[ \left( \frac{N}{2} + n \right)^2 + \frac{N}{2} + n \right] + \frac{w}{2} (2n+1)N \right\}. \quad (1)$$

For the counterbrace, we should obtain, in a similar way, the formula

$$\frac{\sqrt{2}}{2N} \left\{ w_1 \left[ \left( \frac{N}{2} - n \right)^2 - \frac{N}{2} + n \right] - \frac{wN}{2} (2n+1) \right\},$$

which represents tension when it is positive. Proceed in a similar way for the other members.

When there is more than one system, we must divide the truss into its component systems; and when there is ambiguity, we must use, in determining the dimensions of each member, the greatest stress that can possibly come upon it.

## CHAPTER V.

## CENTRE OF GRAVITY.

§ 161. The centre of gravity of a body or system of bodies, is that point through which the resultant of the system of parallel forces that constitutes the weight of the body or system of bodies always passes, whatever be the position in which the body is placed with reference to the direction of the forces.

§ 162. **Centre of Gravity of a System of Bodies.**—If we have a system of bodies whose weights are  $W_1, W_2, W_3$ , etc., the co-ordinates of their individual centres of gravity being  $(x_1, y_1, z_1), (x_2, y_2, z_2), (x_3, y_3, z_3)$ , etc., respectively, and if we denote by  $x_0, y_0, z_0$ , the co-ordinates of the centre of gravity of the system, we should obtain, just as in the determination of the centre of any system of parallel forces, —

1°. By turning all the forces parallel to  $OZ$ , and taking moments about  $OY$ ,

$$(W_1 + W_2 + W_3 + \text{etc.})x_0 = W_1x_1 + W_2x_2 + W_3x_3 + \text{etc.},$$

or

$$x_0 \Sigma W = \Sigma Wx;$$

and, taking moments about  $OX$ ,

$$(W_1 + W_2 + W_3 + \text{etc.})y_0 = W_1y_1 + W_2y_2 + W_3y_3 + \text{etc.},$$

or

$$y_0 \Sigma W = \Sigma Wy.$$

2°. By turning all the forces parallel to  $OX$ , and taking moments about  $OY$ ,

$$(W_1 + W_2 + W_3 + \text{etc.})x_0 = W_1x_1 + W_2x_2 + W_3x_3 + \text{etc.},$$

or

$$x_0 \Sigma W = \Sigma Wx.$$

Hence we have, for the co-ordinates of the centre of gravity of the system,

$$x_0 = \frac{\Sigma Wx}{\Sigma W}, \quad y_0 = \frac{\Sigma Wy}{\Sigma W}, \quad z_0 = \frac{\Sigma Wz}{\Sigma W}.$$

#### EXAMPLES.

1. Suppose a rectangular, homogeneous plate of brass (Fig. 125), where  $AD = 12$  inches,  $AB = 5$  inches, and whose weight is 2 lbs., to have weights attached at the points  $A$ ,  $B$ ,  $C$ , and  $D$  respectively, equal to 8, 6, 5, and 3 lbs.; find the centre of gravity of the system.

FIG. 125.

*Solution.*

Assume the origin of co-ordinates at the centre of the rectangle, and we have

$$\begin{aligned} W_1 &= 2, & W_2 &= 8, & W_3 &= 6, & W_4 &= 5, & W_5 &= 3, \\ x_1 &= 0, & x_2 &= 6, & x_3 &= 6, & x_4 &= -6, & x_5 &= -6, \\ y_1 &= 0, & y_2 &= \frac{5}{2}, & y_3 &= -\frac{5}{2}, & y_4 &= -\frac{5}{2}, & y_5 &= \frac{5}{2}; \end{aligned}$$

$$\therefore \Sigma Wx = 0 + 48 + 36 - 30.0 - 18.0 = 36,$$

$$\Sigma Wy = 0 + 20 - 15 - 12.5 + 7.5 = 0,$$

$$\Sigma W = 2 + 8 + 6 + 5.0 + 3.0 = 24;$$

$$\therefore x_0 = \frac{36}{24} = 1.5, \quad y_0 = \frac{0}{24} = 0.$$

Hence the centre of gravity is situated at a point  $E$  on the line  $OX$ , where  $OE = 1.5$ .

2. Given a uniform circular plate of radius 8, and weight 3 lbs. (Fig. 126). At the points  $A$ ,  $B$ ,  $C$ , and  $D$ , weights are attached equal to 10, 15, 25, and 23 lbs. respectively, also given  $AB = 45^\circ$ ,  $BC = 105^\circ$ ,  $CD = 120^\circ$ ; find the centre of gravity of the system.

FIG. 126.

§ 163. **Centre of Gravity of Homogeneous Bodies.** — For the case of a single homogeneous body, the formulæ have been already deduced in § 44. They are

$$x_o = \frac{\int x dV}{\int dV}, \quad y_o = \frac{\int y dV}{\int dV}, \quad z_o = \frac{\int z dV}{\int dV};$$

and for the weight of the body,

$$W = w \int dV,$$

where  $x_o$ ,  $y_o$ ,  $z_o$  are the co-ordinates of the centre of gravity of the body,  $W$  its weight, and  $w$  its weight per unit of volume.

From these formulæ we can readily deduce those for any special cases; thus, —

(a) *For a volume* referred to rectangular co-ordinate axes,  $dV = dx dy dz$ .

$$x_o = \frac{\iiint x dx dy dz}{\iiint dx dy dz}, \quad y_o = \frac{\iiint y dx dy dz}{\iiint dx dy dz}, \quad z_o = \frac{\iiint z dx dy dz}{\iiint dx dy dz}.$$

(b) *For a flat plate of uniform thickness,  $t$* , the centre of gravity is in the middle layer; hence only two co-ordinates are required to determine it. If it be referred to a system of rectangular axes in the middle plane,  $dV = t dx dy$ ,

$$x_o = \frac{\iint x dx dy}{\iint dx dy}, \quad y_o = \frac{\iint y dx dy}{\iint dx dy}.$$

The centre of gravity of such a thin plate is also called the centre of gravity of the plane area that constitutes the middle plane section; hence —

(c) *For a plane area* referred to rectangular co-ordinate axes in its own plane,

$$x_0 = \frac{\int \int x dx dy}{\int \int dx dy}, \quad y_0 = \frac{\int \int y dx dy}{\int \int dx dy}.$$

(d) *For a slender rod of uniform sectional area,  $a$ ,* if  $x, y, z$ , be the co-ordinates of points on the axis (straight or curved) of the rod, we shall have  $dV = ads = a\sqrt{(dx)^2 + (dy)^2 + (dz)^2}$ ,

$$x_0 = \frac{\int x ds}{\int ds} = \frac{\int x \sqrt{1 + \left(\frac{dy}{dx}\right)^2 + \left(\frac{dz}{dx}\right)^2} dx}{\int \sqrt{1 + \left(\frac{dy}{dx}\right)^2 + \left(\frac{dz}{dx}\right)^2} dx}$$

$$y_0 = \frac{\int y ds}{\int ds} = \frac{\int y \sqrt{1 + \left(\frac{dy}{dx}\right)^2 + \left(\frac{dz}{dx}\right)^2} dx}{\int \sqrt{1 + \left(\frac{dy}{dx}\right)^2 + \left(\frac{dz}{dx}\right)^2} dx}$$

$$z_0 = \frac{\int z ds}{\int ds} = \frac{\int z \sqrt{1 + \left(\frac{dy}{dx}\right)^2 + \left(\frac{dz}{dx}\right)^2} dx}{\int \sqrt{1 + \left(\frac{dy}{dx}\right)^2 + \left(\frac{dz}{dx}\right)^2} dx}$$

(e) *For a slender rod whose axis lies wholly in one plane,* the centre of gravity lies, of course, in the same plane; and if our co-ordinate axes be taken in this plane, we shall have  $z = 0$

$\therefore \frac{dz}{dx} = 0$ , and also  $z_0 = 0$ . Hence we need only two co-

ordinates to determine the centre of gravity, hence  $dV = ads$   
 $= a\sqrt{(dx)^2 + (dy)^2}$ .

$$x_o = \frac{\int x ds}{\int ds} = \frac{\int x \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx}{\int \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx},$$

$$y_o = \frac{\int y ds}{\int ds} = \frac{\int y \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx}{\int \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx}.$$

(f) For a line, straight or curved, which lies entirely in one plane, we shall have, again,

$$x_o = \frac{\int x ds}{\int ds} = \frac{\int x \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx}{\int \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx},$$

$$y_o = \frac{\int y ds}{\int ds} = \frac{\int y \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx}{\int \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx}.$$

Whenever the body of which we wish to determine the centre of gravity is made up of simple figures, of which we already know the positions of the centres of gravity, the method explained in § 162 should be used, and not the formulæ that involve integration; i.e., taking moments about any given line will give us the perpendicular distance of the centre of gravity from that line.

In the case of the determination of the strength and stiffness of beams, it is necessary to know the distance of a horizontal line passing through the centre of gravity of the section,

from the top or the bottom of the section ; but it is of no practical importance to know the position of the centre of gravity on this line. In most of the examples that follow, therefore, the results given are these distances. These examples should be worked out by the student.

In the case of wrought-iron beams of various sections, on account of the thinness of the iron, a sufficiently close approximation is often obtained by considering the cross-section as composed of its central lines ; the area of any given portion being found by multiplying the thickness of the iron by the corresponding length of line, the several areas being assumed to be concentrated in single lines.

#### EXAMPLES.

1. *Straight Line AB* (Fig. 127). — The centre of gravity is evidently at the middle of the line, as this is a point of symmetry.

FIG. 127.

2. *Combination of Two Straight Lines.* — The centre of gravity in each case lies on the line  $OO_1$ , Figs. 128, 129, 130, and 131.

- (a) *Angle-Iron of Unequal Arms* (Fig. 128). — Length  $AB = b$ , length  $BC = h$ , area  $AB = A$ , area  $BC = B$ ;

$$\therefore BE = DE = \frac{1}{2} \frac{bh}{\sqrt{b^2 + h^2}}.$$

FIG. 128.

- (b) *Angle-Iron of Equal Arms* (Fig. 129). — Length  $AB = BC = b$ ;

FIG. 129.

$$\therefore BE = DE = \frac{b}{2\sqrt{2}} = \frac{b}{4}\sqrt{2}.$$

(c) *Cross of Equal Arms* (Fig. 130).— $AB = OO_1 = h$ ;

$$\therefore AC = BC = \frac{h}{2}.$$

FIG. 130.

(d) *T-Iron* (Fig. 131).—Area  $AB = A$ , area  $CE = B$ , length  $CE = h$ ;

FIG. 131.

$$\therefore DE = \frac{Bh}{2(A+B)},$$

$$CD = \frac{2A+B}{2(A+B)}h.$$

3. *Combination of Three Lines*.— $OO_1$  = line passing through the centre of gravity.

(a) *Thin Isosceles Triangular Cell* (Fig. 132).—Length  $AB = BC = a$ , length  $AC = b$ , area  $AB = BC = A$ , area  $AC = B$ ;

FIG. 132.

$$\therefore DB = \sqrt{a^2 - \frac{b^2}{4}} \\ = \frac{1}{2}\sqrt{(2a-b)(2a+b)}$$

$$\therefore DE = \frac{A}{2(2A+B)}\sqrt{(2a-b)(2a+b)},$$

$$BE = \frac{A+B}{2(2A+B)}\sqrt{(2a-b)(2a+b)}.$$

(b) *Same in Different Position* (Fig. 133).

FIG. 133.

$$BD = DC = \frac{b}{2}.$$

(c) *Channel-Iron* (Fig. 134).—Area of flanges =  $A$ , area of web =  $B$ , depth of flanges +  $\frac{1}{2}$  thickness of web =  $h$ ;

FIG. 134.

$$\therefore CE = \frac{Ah}{A+B}$$

$$DE = \frac{h}{2} \frac{A+2B}{A+B}$$

(d) *I-Beam* (Fig. 135).—Area of upper flange =  $A_1$ , area of lower flange =  $A_2$ , area of web =  $B$ , height =  $h$ .

$$CG = \frac{h}{2} \frac{2A_1 + B}{A_1 + A_2 + B}$$

$$GD = \frac{h}{2} \frac{2A_1 + B}{A_1 + A_2 + B}$$

FIG. 135.

4. *Combination of Four Lines*.— $OO_1$  = line passing through the centre of gravity.

(a) *Thin Rectangular Cell* (Fig. 136).—Length  $AB = h$ ;

FIG. 136.

$$\therefore AE = BE = \frac{h}{2}$$

(b) *Thin Square Cell* (Fig. 137).— $AB = BC = h$ ;

$$\therefore BE = CE = \frac{h}{2}$$

FIG. 137.

5. *Circular Arcs*.

(a) *Circular Arc AB* (Fig. 138).—Angle  $AOB = \theta$ , radius =  $r$ .

Use formula

$$x_o = \frac{\int x ds}{\int ds}, \quad y_o = \frac{\int y ds}{\int ds};$$

but use polar co-ordinates, where

$$ds = r d\theta, \quad x = r \cos \theta, \quad y = r \sin \theta,$$

FIG. 138.

$$\therefore x_o = \frac{r^2 \int_0^{\theta_1} \cos \theta d\theta}{r \int_0^{\theta_1} d\theta} = r \frac{(\sin \theta_1)}{\theta_1},$$

$$y_o = \frac{r^2 \int_0^{\theta_1} \sin \theta d\theta}{r \int_0^{\theta_1} d\theta} = r \frac{(1 - \cos \theta_1)}{\theta_1} = 2r \frac{\sin^2 \frac{1}{2} \theta_1}{\theta_1}.$$

(b) *Circular Arc AC* (same figure).

$$x_o = \frac{r \sin \theta_1}{\theta_1}, \quad y_o = 0.$$

(c) *Quarter-Arc of Circle AB, Radius r* (Fig. 139).

$$x_o = \frac{r^2 \int_0^{\frac{\pi}{2}} \cos \theta d\theta}{r \int_0^{\frac{\pi}{2}} d\theta} = \frac{2r}{\pi}$$

$$y_o = \frac{2r}{\pi}$$

FIG. 139.

(d) *Semi-circumference ABC* (same figure).

$$x_o = \frac{2r}{\pi}, \quad y_o = 0.$$

## 6. Combination of Circles and Straight Lines.

*Barlow Rail* (Fig. 140). — Two quadrants, radius  $r$ , and web, whose area =  $\frac{2}{11}$  the united area of the quadrants. Let united area of quadrants =  $A$ , area of web =  $\frac{2}{11}A$ ; let  $EF = x_o$ :

FIG. 140.

$$\pi = \frac{2}{11},$$

$$\therefore \frac{2}{11}Ax_o = A\left(\frac{2r}{\pi}\right) = \frac{2}{11}Ar \quad \therefore x_o = \frac{r}{2} = EF.$$

## 7. Areas.

(a) *T-Section* (Fig. 141).— Let length  $AB = B$ ,  $EF = b$ , entire height  $= H$ ,  $GE = h$ . Let distance of centre of gravity below  $AB = x_1$ ; therefore, taking moments about  $AB$  as an axis,

FIG. 141.

$$x_1 \{ BH - h(B - b) \} = \frac{1}{2} BH^2 - h(B - b) \left( H - \frac{h}{2} \right),$$

whence we can readily derive  $x_1$ .

(b) *I-Section* (Fig. 142).— Let  $AB = B$ ,  $GH = b$ ,  $MN = b_1$ , entire height  $= H$ ,  $BC = H - h$ ,  $EH = h_1$ ; and let  $x_1 =$  distance of centre of gravity below  $AB$ .

Hence, taking moments about  $AB$ , we have

$$\begin{aligned} x_1 \{ B(H - h) + b_1(h - h_1) + bh_1 \} \\ = \frac{B}{2}(H - h)^2 + bh_1 \left( H - \frac{h_1}{2} \right) \\ + b_1(h - h_1) \left( H - h + \frac{h - h_1}{2} \right), \end{aligned}$$

FIG. 142.

whence we can deduce  $x_1$ .

(c) *Triangle* (Fig. 143).— If we consider the triangle  $OBC$  as composed of an indefinite number of narrow strips parallel to the side  $CB$ , of which  $FLHK$  is one, the centre of gravity of each one of these strips will be on the line  $OD$  drawn from  $O$  to the middle point of the side  $CB$ ; hence the centre of gravity of the entire triangle must be on the line  $OD$ . For a similar reason, it must be on the median line  $CE$ ; hence the centre of gravity must be at the intersection of the median lines, and hence

FIG. 143.

$$x_0 = OG = \frac{2}{3} OD. \text{ Moreover, area} = \frac{BC \cdot OD \sin ODC}{2}$$

(d) *Trapezoid* (Fig. 144).

*Graphical Solution.*—Bisect  $AB$  in  $O$ , and  $CE$  in  $D$ ; join  $O$  and  $D$ ; consider the trapezoid to be divided into two triangles,  $ABC$  and  $CEB$ ; let  $g_1$  be the centre of gravity of  $CEB$ , and  $g_2$  that of  $ABC$ . Then will

$$DG_1 = G_1G_2 = OG_2 = \frac{1}{3}OD,$$

FIG. 144.

where  $G, g_1 \parallel G, g_2 \parallel AB$ . Then will  $G$ , the centre of gravity of the trapezoid, be on the line  $g_1g_2$ , at such a point as shall make

$$\frac{Gg_1}{Gg_2} = \frac{ABC}{CEB}$$

But a similar reasoning to that used in the case of the triangle will show that it must be on the line  $OD$ ; hence it must be at the intersection of  $OD$  and  $g_1g_2$ . This gives a graphical construction, and from this we can deduce the value of  $OG$  as follows:—

From the similarity of  $GG_1g_1$  and  $GG_2g_2$  we have

$$\frac{GG_1}{GG_2} = \frac{Gg_1}{Gg_2} = \frac{ABC}{BEC} = \frac{AB}{CE} = \frac{B}{b},$$

since the triangles  $ABC$  and  $CEB$  have the same altitude: hence, from the proportion  $\frac{GG_1}{GG_2} = \frac{B}{b}$ , we have

$$\frac{GG_2}{G_1G_2} = \frac{b}{B+b};$$

but  $G_1G_2 = \frac{OD}{3}$ , and hence

$$OG = OG_2 + GG_2 = \frac{OD}{3} + GG_2 = \frac{OD}{3} \left( 1 + \frac{b}{B+b} \right).$$

(c) *Parabolic Half-Segment* OAB (Fig. 145).—Let  $OA = x_1$ ,  $AB = y_1$ ; let  $x_0, y_0$  be the co-ordinates of the centre of gravity; let the equation of the parabola be  $y^2 = 4ax$ :

FIG. 145.

$$\therefore x_0 = \frac{\int_0^{2a^{\frac{1}{2}}x_1^{\frac{1}{2}}} \int_0^{x_1} x dx dy}{\int_0^{2a^{\frac{1}{2}}x_1^{\frac{1}{2}}} \int_0^{x_1} dx dy} = \frac{2a^{\frac{1}{2}} \int_0^{x_1} x^{\frac{3}{2}} dx}{2a^{\frac{1}{2}} \int_0^{x_1} x^{\frac{1}{2}} dx} = \frac{\frac{2}{5} x_1^{\frac{5}{2}}}{\frac{2}{3} x_1^{\frac{3}{2}}} = \frac{3}{5} x_1.$$

$$y_0 = \frac{\int_0^{2a^{\frac{1}{2}}x_1^{\frac{1}{2}}} \int_0^{x_1} y dx dy}{\int_0^{2a^{\frac{1}{2}}x_1^{\frac{1}{2}}} \int_0^{x_1} dx dy} = \frac{2}{5} a^{\frac{1}{2}} x_1^{\frac{5}{2}} = \frac{3}{5} y_1.$$

$$\text{Area} = \int_0^{2a^{\frac{1}{2}}x_1^{\frac{1}{2}}} \int_0^{x_1} dx dy = \frac{4}{5} a^{\frac{1}{2}} x_1^{\frac{5}{2}} = \frac{3}{5} (2a^{\frac{1}{2}} x_1^{\frac{1}{2}}) x_1 = \frac{3}{5} x_1 y_1.$$

(f) *Parabolic Spandril* OBC (Fig. 145).—Let  $x_0, y_0$  be co-ordinates of centre of gravity of the spandril.

$$x_0 = \frac{\int_{2a^{\frac{1}{2}}x_1^{\frac{1}{2}}}^{y_1} \int_0^{x_1} x dx dy}{\int_{2a^{\frac{1}{2}}x_1^{\frac{1}{2}}}^{y_1} \int_0^{x_1} dx dy} = \frac{3}{10} x_1,$$

$$y_0 = \frac{\int_{2a^{\frac{1}{2}}x_1^{\frac{1}{2}}}^{y_1} \int_0^{x_1} y dx dy}{\int_{2a^{\frac{1}{2}}x_1^{\frac{1}{2}}}^{y_1} \int_0^{x_1} dx dy} = \frac{3}{4} y_1,$$

$$\text{Area} = x_1 y_1 - \frac{3}{5} x_1 y_1 = \frac{2}{5} x_1 y_1.$$

(g) *Circular Sector OAC* (Fig. 146).—Let  $OA = r$ ,  $AOX = \theta_1$ ,  $x_o, y_o$  be the co-ordinates of the centre of gravity;

$$\begin{aligned} \therefore y_o &= 0, \\ x_o &= \frac{\int_{-\sqrt{r^2-x^2}}^{\sqrt{r^2-x^2}} \int_{r \cos \theta_1}^r x dx dy + \int_{-x \tan \theta_1}^{x \tan \theta_1} \int_0^{r \cos \theta_1} x dx dy}{\frac{1}{2}r(2r\theta_1)} \\ &= \frac{1}{3}r \frac{\sin \theta_1}{\theta_1}, \end{aligned}$$

FIG. 146.

$$\text{Area} = \frac{1}{2}r(2r\theta_1) = r^2\theta_1.$$

*Second Solution.*

Consider the sector to be made up of an indefinite number of narrow rings; let  $\rho$  be the variable radius, and  $d\rho$  the thickness;

$$\therefore \text{Elementary area} = 2\rho\theta_1 d\rho,$$

and centre of gravity of this elementary area is on  $OX$ , at a distance from  $O$  equal to  $\rho \frac{\sin \theta_1}{\theta_1}$  [see Example 5 (b)];

$$\therefore x_o = \frac{\int_0^r \left\{ \rho \frac{\sin \theta_1}{\theta_1} \right\} \{ 2\rho\theta_1 d\rho \}}{\int_0^r 2\rho\theta_1 d\rho} = \frac{2 \sin \theta_1 \int_0^r \rho^2 d\rho}{2\theta_1 \int_0^r \rho d\rho} = \frac{1}{3}r \frac{\sin \theta_1}{\theta_1}.$$

(h) *Circular Half-Segment ABX* (Fig. 146).

$$\begin{aligned} x_o &= \frac{\int_0^r \int_{r \cos \theta_1}^{\sqrt{r^2-x^2}} x dx dy}{\text{Sector minus triangle}} = \frac{\int_{r \cos \theta_1}^r x \sqrt{r^2-x^2} dx}{\frac{1}{2}r^2\theta_1 - \frac{1}{2}r^2 \sin \theta_1 \cos \theta_1} \\ &= \frac{1}{3}r \frac{\sin^3 \theta_1}{\theta_1 - \sin \theta_1 \cos \theta_1}, \\ y_o &= \frac{\int_0^r \int_{r \cos \theta_1}^{\sqrt{r^2-x^2}} y dx dy}{\frac{1}{2}r^2(\theta_1 - \sin \theta_1 \cos \theta_1)} = \frac{1}{3}r \frac{4 \sin^2 \frac{1}{2} \theta_1 - \sin^2 \theta_1 \cos \theta_1}{\theta_1 - \sin \theta_1 \cos \theta_1}. \end{aligned}$$

§ 164. **Pappus's Theorems.** — The following two theorems serve often to simplify the determination of the centres of gravity of lines and areas. They are as follows : —

**THEOREM I.** — If a plane curve lies wholly on one side of a straight line in its own plane, and, revolving about that line, generates thereby a surface of revolution, the area of the surface is equal to the product of the length of the revolving line, and of the path described by its centre of gravity.

*Proof.* — Let the curve lie in the  $xy$  plane, and let the axis of  $y$  be the line about which it revolves. We have, from what precedes, § 163 (e),  $x_0 = \frac{\int x ds}{\int ds}$  ;

$$\therefore x_0 \int ds = \int x ds,$$

where  $x_0$  equals the perpendicular distance of the centre of gravity of the curve from  $OY$ ,  $ds$  = elementary arc,

$$\therefore 2\pi x_0 \int ds = \int (2\pi x) ds ;$$

or, reversing the equation,

$$\int (2\pi x) ds = (2\pi x_0) s.$$

But  $\int (2\pi x) ds$  = surface described in one revolution, while  $s$  = length of arc, and  $2\pi x_0$  = path described by the centre of gravity in one revolution. Hence follows the proposition.

**THEOREM II.** — If a plane area lying wholly on the same side of a straight line in its own plane revolves about that line, and thereby generates a solid of revolution, the volume of the solid thus generated is equal to the product of the revolving area, and of the path described by the centre of gravity of the plane area during the revolution.

*Proof.* — Let the area lie in the  $xy$  plane, and let the axis  $OY$  be the axis of revolution. We then have, from what has preceded, if  $x_0$  = perpendicular distance of the centre of gravity of the plane area from  $OY$ , the equation, § 163 (b),

$$x_0 = \frac{\iint x dx dy}{\iint dx dy}.$$

Hence

$$x_0 \iint dx dy = \iint x dx dy;$$

$$\therefore (2\pi x_0) \iint dx dy = \iint (2\pi x) dx dy$$

or

$$\iint (2\pi x) dx dy = 2\pi x_0 \iint dx dy.$$

But  $\iint (2\pi x) dx dy$  = volume described in one revolution, and  $2\pi x_0$  = path described by the centre of gravity in one revolution. Hence follows the proposition.

The same propositions hold true for any part of a revolution, as well as for an entire revolution, since we might have multiplied through by the circular measure  $\theta$ , instead of by  $2\pi$ .

It is evident that the first of these two theorems may be used to determine the centre of gravity of a line, when the length of the line, and the surface described by revolving it about the axis, are known; and so also that the second theorem may be used to determine the centre of gravity of a plane area whenever the area is known, and also the volume described by revolving it around the axis.

#### EXAMPLES.

1. *Circular Arc* AC (Fig. 138). — Length of arc =  $s = 2r\theta$ , surface of zone described by revolving it about  $OY$  = circumference of a great circle multiplied by the altitude =  $(2\pi r)(2r \sin \theta_1)$ ;

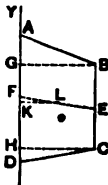

$$\therefore (2\pi x_0)(2r\theta_1) = (2\pi r)(2r \sin \theta_1) \quad \therefore x_0 \theta_1 = r \sin \theta_1$$

$$\therefore x = r \frac{\sin \theta_1}{\theta_1}.$$

2. *Semicircular Arc* (Fig. 139).—Length of arc =  $\pi r$ , surface of sphere described =  $4\pi r^2$ ;

$$\therefore 2\pi x_0(\pi r) = 4\pi r^2 \quad \therefore x_0 = \frac{2r}{\pi}.$$

3. *Trapezoid* (Fig. 147).—Let  $AD = a$ ,  $BC = b$ ; let it revolve around  $AD$ : it generates two cones and a cylinder.

Area of trapezoid =  $\frac{AD + BC}{2} BG$ ,  
 Volume =  $\frac{\pi(GB)^2}{3}(AG + HD) + \pi(GB)^2 \cdot BC$   
 $= \frac{\pi(GB)^2}{3}(AG + HD + 3BC)$   
 $= \frac{\pi(GB)^2}{3}(AD + BC + BC)$

$$\therefore (2\pi x_0) \left( \frac{AD + BC}{2} \right) \cdot GB = \frac{\pi(GB)^2}{3} \{ (AD + BC) + BC \}$$

$$\therefore x_0 = \frac{GB}{3} \left( 1 + \frac{BC}{AD + BC} \right) = \frac{GB}{3} \left( 1 + \frac{b}{a + b} \right) = KL$$

$$\therefore FL = \frac{FE}{3} \left( 1 + \frac{b}{a + b} \right).$$

4. *Circular Sector* ACO (Fig. 146).—Area of sector =  $r^2\theta$ , volume described =  $\frac{1}{3}r(\text{surface of zone}) = \frac{1}{3}r(2\pi r)(2r \sin \theta) = \frac{4}{3}\pi r^3 \sin \theta$ ;

$$\therefore (2\pi x_0)(r^2\theta) = \frac{4}{3}\pi r^3 \sin \theta \quad \therefore x_0 = \frac{2}{3}r \frac{\sin \theta}{\theta}.$$

§ 165. *Centre of Gravity of Solid Bodies.*—The general formulæ furnish, in most cases, a very complicated solution, and hence we generally have recourse to some simpler method. A few examples will be given in this and the next section.

**Tetrahedron**  $ABCD$  (Fig. 148).—The plane  $ABE$ , containing the edge  $AB$  and the middle point  $E$  of the edge  $CD$ , bisects all lines drawn parallel to  $CD$ , and terminating in the faces  $ABD$  and  $ABC$ : hence a similar reasoning to that used in the case of the triangle will show that the centre of gravity of the pyramid must be in the plane  $ABE$ ; in the same way it may be shown that it must lie in the plane  $ACF$ . Hence it must lie in their intersection, or in the line  $AG$  joining the vertex  $A$  with the centre of gravity (intersection of the medians) of the opposite face. In the same way it can be shown that the centre of gravity of the triangular pyramid must lie in the line drawn from the vertex  $B$  to the centre of gravity of the face  $ACD$ . Hence the centre of gravity of the tetrahedron will be found on the line  $AG$  at a distance from  $G$  equal to  $\frac{1}{4}AG$ .

FIG. 148.

§ 166. **Centre of Gravity of Bodies which are Symmetrical with Respect to an Axis.**—Such solids may be generated by the motion of a plane figure, as  $ABCD$  (Fig. 149), of variable dimensions, and of any form whose centre  $G$  remains upon the axis  $OX$ ; its plane being always perpendicular to  $OX$ , and its variable area  $X$  being a function of  $x$ , its distance from the origin.

FIG. 149.

Here the centre of gravity will evidently lie on the axis  $OX$ , and the elementary volume will be the volume of a thin plate whose area is  $X$  and thickness  $\Delta x$ ; hence the elementary volume will be  $X\Delta x$ .

Take moments about  $OY$ , and we shall have

$$x_0 \int X dx = \int X x dx \quad \text{and} \quad \text{Volume} = \int X dx,$$

or

$$x_0 = \frac{\int X x dx}{\int X dx}, \quad V = \int X dx.$$

## EXAMPLES.

1. *Ellipsoid*  $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$  (Fig. 150).—Find centre of gravity

FIG. 150.

of the half to the right of the  $x$  plane. Let  $OK = x$ . Now if, in the equation of the ellipsoid, we make  $y = 0$ , we have  $\frac{x^2}{a^2} + \frac{z^2}{c^2} = 1$ ;

$$\therefore z = \frac{c}{a}\sqrt{a^2 - x^2},$$

where  $s = EK$ .

Make  $s = 0$  in the equation of the ellipsoid, and  $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ ;

$$\therefore y = \frac{b}{a}\sqrt{a^2 - x^2},$$

where  $y = KG$ ;

$$\therefore EK = \frac{c}{a}\sqrt{a^2 - x^2}, \quad KG = \frac{b}{a}\sqrt{a^2 - x^2},$$

are the semi-axes of the variable ellipse  $EGFH$ , which, by moving along  $OX$ , generates the ellipsoid. Hence

$$\text{Area } EGFH = \pi(EK \cdot GK) = \frac{\pi bc}{a^2}(a^2 - x^2) = X;$$

hence

$$\text{Elementary volume} = \frac{\pi bc}{a^2}(a^2 - x^2)\Delta x.$$

$$\therefore x_0 = \frac{\frac{\pi bc}{a^2} \int_0^a (a^2 x - x^3) dx}{\frac{\pi bc}{a^2} \int_0^a (a^2 - x^2) dx} = \frac{\left\{ \frac{a^2 x^2}{2} - \frac{x^4}{4} \right\}_0^a}{\left\{ a^2 x - \frac{x^3}{3} \right\}_0^a} = \frac{3}{8}a.$$

$$V = \frac{\pi bc}{a^2} \int_0^a (a^2 - x^2) dx = \frac{3}{8}\pi abc.$$

2. *Hemisphere*.—Make  $a = b = c$ , and  $x_0 = \frac{3}{8}a$ ,  $V = \frac{3}{8}\pi a^3$ .

If the section  $X$  were oblique to  $OX$ , making an angle  $\theta$  with it, the elementary volume would not be  $Xdx$ , but  $Xdx \sin \theta$ , and we should have

$$x_0 = \frac{\sin \theta \int Xx dx}{\sin \theta \int X dx} = \frac{\int Xx dx}{\int X dx} \quad \text{and} \quad V = \sin \theta \int X dx.$$

3. *Oblique Cone* (Fig. 151).—Let  $OA = h$ ; let area of base be  $A$ , and let the angle made by  $OX$  with the base be  $\theta$ ;

$$\therefore \frac{X}{A} = \frac{x^2}{h^2} \quad \therefore X = \frac{A}{h^2} x^2$$

$$\therefore x_0 = \frac{\frac{A}{h^2} \int_0^h x^3 dx}{\frac{A}{h^2} \int_0^h x^2 dx} = \frac{\frac{h^4}{4}}{\frac{h^3}{3}} = \frac{3}{4}h.$$

FIG. 151.

$$V = \sin \theta \int X dx = \frac{A}{h^2} \sin \theta \int_0^h x^2 dx = \frac{1}{3} Ah \sin \theta.$$

4. *Truncated Cone* (Fig. 151).—Let height of entire cone be  $h = OA$ ; let height of portion cut off be  $h_1$ ;

$$\therefore x_0 = \frac{\frac{A}{h^2} \int_{h_1}^h x^3 dx}{\frac{A}{h^2} \int_{h_1}^h x^2 dx} = \frac{\frac{h^4 - h_1^4}{4}}{\frac{h^3 - h_1^3}{3}} = \frac{3}{4} \frac{h^4 - h_1^4}{h^3 - h_1^3}.$$

$$V \frac{A}{h^2} \sin \theta \int_{h_1}^h x^2 dx = \frac{Ah \sin \theta}{3h^3} (h^3 - h_1^3) = \frac{1}{3} Ah \sin \theta \left(1 - \frac{h_1^3}{h^3}\right).$$

## CHAPTER VI.

## STRENGTH OF MATERIALS.

§ 167. **Stress, Strain, and Modulus of Elasticity.**—When a body is subjected to the action of external forces, if we imagine a plane section dividing the body into two parts, the force with which one part of the body acts upon the other at this plane is called the *stress* on the plane; and, in order to know it completely, we must know its distribution and its direction at each point of the plane. If we consider a small area lying in this plane, including the point  $O$ , and represent the stress on this area by  $p$ , whereas the area itself is represented by  $a$ , then will the limit of  $\frac{p}{a}$  as  $a$  approaches zero be the intensity of the stress on the plane under consideration at the point  $O$ .

When a body is subjected to the action of external forces, and, in consequence of this, undergoes a change of form, it will be found that lines drawn within the body are changed, by the action of these external forces, in length, in direction, or in both; and the entire change of form of the body may be correctly described by describing a sufficient number of these changes.

If we join two points,  $A$  and  $B$ , of a body before the external forces are applied, and find, that, after the application of the external forces, the line joining the same two points of the body has undergone a change of length  $\Delta(AB)$ , then is the

limit of the ratio  $\frac{\Delta(AB)}{AB}$  as  $AB$  approaches zero called the strain of the body at the point  $A$  in the direction  $AB$ .

If  $AB + \Delta(AB) > AB$ , the strain is one of tension.

If  $AB + \Delta(AB) < AB$ , the strain is one of compression.

Suppose a straight rod of uniform section  $A$  to be subjected to a pull  $P$  in the direction of its length, and that this pull is uniformly distributed over the cross-section : then will the intensity of the stress on the cross-section be

$$p = \frac{P}{A}.$$

If  $P$  be measured in pounds, and  $A$  in square inches, then will  $p$  be measured in pounds per square inch.

If the length of the rod before the load is applied be  $l$ , and its length after the load is applied be  $l + e$ , then is  $e$  the elongation of the rod; and if this elongation is uniform throughout the length of the rod, then is  $\frac{e}{l}$  the elongation of the rod per unit of length, or the strain.

Hence, if  $a$  represent the strain due to the stress  $p$  per unit of area, we shall have

$$a = \frac{e}{l}.$$

The *Modulus of Elasticity* is the quotient obtained by dividing the stress per unit of area by the strain, or

$$E = \frac{p}{a};$$

and this is expressed in units of weight per unit of area, as in pounds per square inch.

The modulus of elasticity is sometimes defined as the weight that would be required to stretch a rod one square inch in section to double its length, if Hooke's law, "The stress is proportional to the strain," held up to that point, and the rod did not break. Of course the modulus of elasticity is a constant for any given material just as far as, and no farther than, Hooke's law holds.

#### EXAMPLES.

1. A wrought-iron rod 10 feet long and 1 inch in diameter is loaded in the direction of its length with 8000 lbs. ; find (1) the intensity of the stress, (2) the elongation of the rod ; assuming the modulus of the iron to be 28000000 lbs. per square inch.

2. What would be the elongation of a similar rod of cast-iron under the same load, assuming the modulus of elasticity of cast-iron to be 17000000 lbs. per square inch ?

3. Given a steel bar, area of section being 4 square inches, the length of a certain portion under a load of 25000 lbs. being 10 feet, and its length under a load of 100000 lbs. being 10' 0".075 ; find the modulus of elasticity of the material.

4. What load will be required to stretch the rod in the first example  $\frac{1}{16}$  inch ?

§ 168. **Resistance to Stretching and Tearing.** — The most-used criterion of safety against injury for a loaded piece is, that the greatest intensity of the stress to which any part of it is subjected shall nowhere exceed a certain fixed amount, called the working-strength of the material ; this working-strength being a certain fraction of the breaking-strength determined by practical considerations.

The more correct but less used criterion is, that the greatest strain in any part of the structure shall nowhere exceed the working-strain ; the greatest allowable amount of strain being a fixed quantity determined by practical considerations.

This is equivalent to limiting the allowable elongation or compression to a certain fraction of its length, or the deflection of a beam to a certain fraction of the span.

If the stress on a plane surface be uniformly distributed, its resultant will evidently act at the centre of gravity of the surface, as has been already shown in § 42 to be the case with any uniformly distributed force.

If a straight rod of uniform section and material be subjected to a pull in the direction of its length, and if the resultant of the pull acts along a line passing through the centres of gravity of the sections of the rod, it is assumed in practice that the stress is uniformly distributed throughout the rod, and hence that for any section we shall obtain the stress per square inch by dividing the total pull by the number of square inches in the section.

If, on the other hand, the resultant of the pull does not act through the centres of gravity of the sections, the pull is not uniformly distributed; and while

$$p = \frac{P}{A}$$

will express the mean stress per square inch, the actual intensity of the stress will vary at different points of the section, being greater than  $\frac{P}{A}$  at some points and less at others. How to determine its greatest intensity in such cases will be shown later.

With good workmanship and well-fitting joints, the first case, or that of a uniformly distributed stress, can be practically realized; but with ill-fitting joints or poor workmanship, or with a material that is not homogeneous, the resultant of the pull is liable to be thrown to one side of the line passing through the centres of gravity of the sections, and thus there

is set up a bending-action in addition to the direct tension, and therefore an unevenly distributed stress.

It is of the greatest importance in practice to take cognizance of any such irregularities, and determine the greatest intensity of the stress to which the piece is subjected: though it is too often taken account of merely by means of a factor of safety; in other words, by guess.

Leaving, then, this latter case until we have studied the stresses due to bending, we will confine ourselves to the case of the uniformly distributed stress.

If the total pull on the rod in the direction of its length be  $P$ , and the area of its cross-section  $A$ , we shall have, for the intensity of the pull,

$$p = \frac{P}{A}.$$

On the other hand, if the working-strength of the material per unit of area be  $f$ , we shall have, for the greatest admissible load to be applied,

$$P = fA.$$

If  $f$  be the working-strength of the material per square inch, and  $E$  the modulus of elasticity, then is the greatest admissible strain equal to

$$\alpha = \frac{f}{E}.$$

Thus, assuming 12000 lbs. per square inch as the working tensile strength of wrought-iron, and 28000000 lbs. per square inch as its modulus of elasticity, its working-strain would be

$$\alpha = \frac{12000}{28000000} = \frac{3}{7000}.$$

Hence the greatest safe elongation of the bar would be  $\frac{3}{7000}$  of its length. Hence a rod 10 feet long could safely be stretched  $\frac{3}{700}$  of a foot = 0.0514".

§ 169. **Approximate Values of Breaking and Working Strength, and of Modulus of Elasticity.**—In a later part of this book the attempt will be made to give an account of the experiments that have been made to determine the strength and elasticity of the materials ordinarily used in construction, in such a way as to enable the student to decide for himself, in any special case, upon the proper values of the constants that he ought to use.

For the present, however, the following will be given as a rough approximation to some of these quantities, which we may make use of in our work until we reach the above-mentioned account.

(a) *Cast-Iron.*

Breaking tensile strength per square inch, of common qualities, 14000 to 20000 lbs.; of gun iron, 30000 to 33000 lbs.

Modulus of elasticity for tension and for compression, about 17000000 lbs. per square inch.

(b) *Wrought-Iron.*

Breaking tensile strength per square inch, from 40000 to 60000 lbs.

Modulus of elasticity for tension and for compression, about 28000000.

(c) *Mild Steel.*

Breaking tensile strength per square inch, 55000 to 70000 lbs.

Modulus of elasticity for tension and for compression, from 28000000 to 30000000 lbs. per square inch.

(d) *Wood.*

Breaking compressive strength per square inch :—

|                              |                   |
|------------------------------|-------------------|
| Oak, green . . . . .         | 3000 lbs.         |
| Oak, dry . . . . .           | 3000 to 6000 lbs. |
| Yellow pine, green . . . . . | 3000 to 4000 lbs. |
| Yellow pine, dry. . . . .    | 4000 to 7000 lbs. |

Modulus of elasticity for compression (average values):—

Oak . . . . . 1300000 lbs. per square inch.

Yellow pine . . . . . 1600000 lbs. per square inch.

§ 170. **Sudden Application of the Load.**—If a wrought-iron rod 10 feet long and 1 square inch in section be loaded with 12000 pounds in the direction of its length, and if the modulus of elasticity of the iron be 28000000, it will stretch 0.0514" provided the load be gradually applied: thus, the rod begins to stretch as soon as a small load is applied; and, as the load gradually increases, the stretch increases, until it reaches 0.0514".

If, on the other hand, the load of 12000 lbs. be suddenly applied (i.e., put on all at once) without being allowed to fall through any height beforehand, it would cause a greater stretch at first, the rod undergoing a series of oscillations, finally settling down to an elongation of 0.0514".

To ascertain what suddenly applied load will produce at most the elongation 0.0514", observe, that, in the case of the gradually applied load, we have a load gradually increasing from

0 to 12000 lbs.

Its mean value is, therefore,  $\frac{1}{2}(12000) = 6000$  lbs.; and this force descends through a distance of

0.0514".

Hence the amount of mechanical work done on the rod by the gradually applied load in producing this elongation is

$$(6000)(0.0514) = 308.4 \text{ inch-lbs.}$$

Hence, if we are to perform upon the rod 308.4 inch-lbs. of work with a constant force, and if the stretch is to be 0.0514", the magnitude of the force must be

$$\frac{308.4}{0.0514} = 6000 \text{ lbs.}$$

Hence a suddenly applied load will produce double the strain that would be produced by the same load gradually applied; and, moreover, a suddenly applied load should be only half as great as one gradually applied if it is to produce the same strain.

§ 171. **Resilience of a Tension-Bar.** — The resilience of a tension-rod is the mechanical work done in stretching it to the same amount that it would stretch under the greatest allowable gradually applied load, and is found by multiplying the greatest allowable load by half the corresponding elongation.

Thus, suppose a load of 100 lbs. to be dropped upon the rod described above in such a way as to cause an elongation not greater than 0.0514", it would be necessary to drop it from a height not greater than 3.08".

#### EXAMPLES.

1. A wrought-iron rod is 12 feet long and 1 inch in diameter, and is loaded in the direction of its length; the working-strength of the iron being 12000 lbs. per square inch, and the modulus of elasticity 28000000 lbs. per square inch.

Find the working-strain.

Find the working-load.

Find the working-elongation.

Find the working-resilience.

From what height can a 50-pound weight be dropped so as to produce tension, without stretching it more than the working-elongation?

2. Do the same for a cast-iron rod, where the working-strength is 5000 pounds per square inch, and the modulus of elasticity 17000000; the dimensions of the rod being the same.

§ 172. **Results of Wöhler's Experiments on Tensile Strength.** — According to the experiments of Wöhler, of which an account will be given later, the breaking-strength of a piece

depends, not only on whether the load is gradually or suddenly applied, but also on the extreme variations of load that the piece is called upon to undergo, and the number of changes to which it is to be submitted during its life.

For a piece which is always in tension, he determines the following two constants; viz.,  $t$ , the carrying-strength per square inch, or the greatest quiescent stress that the piece will bear, and  $u$ , the primitive safe strength, or the greatest stress per square inch of which the piece will bear an indefinite number of repetitions, the stress being entirely removed in the intervals.

This primitive safe strength,  $u$ , is used as the breaking-strength when the stress varies from 0 to  $u$  every time. Then, by means of Launhardt's formula, we are able to determine the ultimate strength per square inch for any different limits of stress, as for a piece that is to be alternately subjected to 80000 and 6000 pounds.

Thus, for Phoenix Company's axle iron, Wöhler finds

$$t = 3290 \text{ kil. per sq. cent.} = 46800 \text{ lbs. per sq. in.,}$$

$$u = 2100 \text{ kil. per sq. cent.} = 30000 \text{ lbs. per sq. in.}$$

Launhardt's formula for the ultimate strength per unit of area is

$$a = u \left\{ 1 + \frac{t - u}{u} \frac{\text{least stress}}{\text{greatest stress}} \right\}.$$

Hence, with these values of  $t$  and  $u$ , we should have, for the ultimate strength per square inch,

$$a = 2100 \left\{ 1 + \frac{1}{2} \frac{\text{least stress}}{\text{greatest stress}} \right\} \text{ kil. per sq. cent.,}$$

or

$$a = 30000 \left\{ 1 + \frac{1}{2} \frac{\text{least stress}}{\text{greatest stress}} \right\} \text{ lbs. per sq. in.}$$

Thus, if least stress = 6000, and greatest = 80000, we should have

$$a = 30000 \left\{ 1 + \frac{1}{2} \cdot \frac{6}{80} \right\} = 30000 \left\{ 1 + \frac{3}{80} \right\} = 31125;$$

if least stress = 60000, and greatest = 80000,

$$a = 30000 \left\{ 1 + \frac{1}{2} \cdot \frac{6}{8} \right\} = 30000 \left\{ 1 + \frac{3}{8} \right\} = 41250;$$

if least stress = greatest stress = 80000,

$$a = 30000 \left\{ 1 + \frac{1}{2} \right\} = 45000 = \text{carrying-strength.}$$

Hence, instead of using, as breaking-strength per square inch in all cases, 45000, we should use a set of values varying from 45000 down to 30000, according to the variation of stress which the piece is to undergo.

For working-strength, Weyrauch divides this by 3: thus obtaining, for working-strength per square inch,

$$b = 10000 \left\{ 1 + \frac{1}{2} \frac{\text{least stress}}{\text{greatest stress}} \right\} \text{ lbs. per sq. in. ;}$$

for Krupp's cast-steel,

$$t = 7340 \text{ kil. per sq. cent.} = 104400 \text{ lbs. per sq. in.,}$$

$$u = 3300 \text{ kil. per sq. cent.} = 46900 \text{ lbs. per sq. in. ;}$$

$$\therefore a = 3300 \left\{ 1 + \frac{2}{11} \frac{\text{least stress}}{\text{greatest stress}} \right\} \text{ kil. per sq. cent.,}$$

or

$$a = 46900 \left\{ 1 + \frac{2}{11} \frac{\text{least stress}}{\text{greatest stress}} \right\} \text{ lbs. per sq. in.,}$$

$$\therefore b = 15633 \left\{ 1 + \frac{2}{11} \frac{\text{least stress}}{\text{greatest stress}} \right\} \text{ lbs. per sq. in.}$$

#### EXAMPLES.

Find the breaking-strength per square inch for a wrought-iron tension-rod.

1. Extreme loads are 75000 and 6000 lbs.
  2. Extreme loads are 120000 and 100000 lbs.
  3. Extreme loads are 300000 and 10000 lbs.
- Find the safe section for the rod in each case.

§ 173. **Suspension-Rod of Uniform Strength.**—In the case of a long suspension-rod, the weight of the rod itself sometimes becomes an important item. The upper section must, of course, be large enough to bear the weight that is hung from the rod plus the weight of the rod itself; but it is sometimes desirable to diminish the sections as they descend. This is often accomplished in mines by making the rod in sections, each section being calculated to bear the weight below it plus its own weight.

Were the sections gradually diminished, so that each section would be just large enough to support the weight below it, we should, of course, have a curvilinear form; and the equation of this curve could be found as follows, or, rather, the area of any section at a distance from the bottom of the rod.

Let  $W$  = weight hung at  $O$  (Fig. 152),

FIG. 152.

Let  $w$  = weight per unit of volume of the rod,

Let  $x$  = distance  $AO$ ,

Let  $S$  = area of section  $A$ ,

Let  $x + dx$  = distance  $BO$ ,

Let  $S + dS$  = area of section at  $B$ ,

Let  $f$  = working-strength of the material per square inch.

1°. The section at  $O$  must be just large enough to sustain the load  $W$ ;

$$\therefore S_o = \frac{W}{f}$$

2°. The area in  $dS$  must be just enough to sustain the weight of the portion of the rod between  $A$  and  $B$ .

The weight of this portion is  $wSdx$ ;

$$\therefore dS = \frac{wSdx}{f}$$

$$\therefore \frac{dS}{S} = \frac{w}{f} dx \quad \therefore \log_e S = \frac{w}{f} x + \text{a constant.}$$

When  $x = 0$ ,  $S = \frac{W}{f}$ ;

$$\therefore \log_e \frac{W}{f} = \text{the constant}$$

$$\therefore \log_e S - \log_e \left( \frac{W}{f} \right) = \frac{w}{f} x$$

$$\therefore \frac{S}{\left( \frac{W}{f} \right)} = e^{\frac{wx}{f}}$$

$$\therefore S = \frac{W}{f} e^{\frac{wx}{f}}.$$

This gives us the means of determining the area at any distance  $x$  from  $O$ .

#### EXAMPLES.

1. A wrought-iron tension-rod 200 feet long is to sustain a load of 2000 lbs. with a factor of safety of 4, and is to be made in 4 sections, each 50 feet long; find the diameter of each section, the weight of the wrought iron being 480 lbs. per cubic foot.

2. Find the diameter needed if the rod were made of uniform section, also the weight of the extra iron necessary to use in this case.

3. Find the equation of the longitudinal section of the rod, assuming a square cross-section, if it were one of uniform strength, instead of being made in 4 sections.

§ 174. **Thin Hollow Cylinders subjected to an Internal Normal Pressure.** — Let  $p$  denote the uniform intensity of the pressure exerted by a fluid which is confined within a hollow cylinder of radius  $r$  and of thickness  $t$  (Fig. 153), the thickness being small compared with the radius. Let us consider a unit of length of the cylinder, and let us also consider the forces acting on the upper half-ring  $CED$ .

FIG. 153.

The total upward force acting on this half-ring, in consequence of the internal normal pressure, will be the same as that acting on a section of the cylinder made by a plane passing through its axis, and the diameter  $CD$ . The area of this

section will be  $2r \times 1 = 2r$ : hence the total upward force will be  $2r \times p = 2pr$ ; and the tendency of this upward force is to cause the cylinder to give way at  $A$  and  $B$ , the upper part separating from the lower.

This tendency is resisted by the tension in the metal at the sections  $AC$  and  $BD$ ; hence at each of these sections, there has to be resisted a tensile stress equal to  $\frac{1}{2}(2pr) = pr$ . This stress is really not distributed uniformly throughout the cross-section of the metal; but, inasmuch as the metal is thin, no serious error will be made if it be accounted as distributed uniformly. The area of each section, however, is  $t \times 1 = t$ ; therefore, if  $T$  denote the intensity of the tension in the metal in a tangential direction (i.e., the intensity of the hoop tension), we shall have

$$T = \frac{pr}{t}.$$

Hence, to insure safety,  $T$  must not be greater than  $f$ , the working-strength of the material for tension; hence, putting

$$f = \frac{pr}{t},$$

we shall have

$$t = \frac{pr}{f}$$

as the proper thickness, when  $p$  = normal pressure per square inch, and radius =  $r$ .

The above are the formulæ in common use for the determination of the thickness of the shell of a steam-boiler; for in that case the steam-pressure is so great that the tension induced by any shocks that are likely to occur, or by the weight of the boiler, is very small in comparison with that induced by the steam-pressure. On the other hand, in the case of an ordinary water-pipe, the reverse is the case.

To provide for this case, Weisbach directs us to add to the thickness we should obtain by the above formulæ, a constant minimum thickness.

The following are his formulæ,  $d$  being the diameter in inches,  $p$  the internal normal pressure in pounds per square inch, and  $t$  the thickness in inches. For tubes made of

|                            |                            |
|----------------------------|----------------------------|
| Sheet-iron . . . . .       | $t = 0.00086 \, pd + 0.12$ |
| Cast-iron . . . . .        | $t = 0.00238 \, pd + 0.34$ |
| Copper . . . . .           | $t = 0.00148 \, pd + 0.16$ |
| Lead . . . . .             | $t = 0.00507 \, pd + 0.21$ |
| Zinc . . . . .             | $t = 0.00242 \, pd + 0.16$ |
| Wood . . . . .             | $t = 0.03230 \, pd + 1.07$ |
| Natural stone : . . . . .  | $t = 0.03690 \, pd + 1.18$ |
| Artificial stone . . . . . | $t = 0.05380 \, pd + 1.58$ |

§ 175. **Resistance to Direct Compression.** — When a piece is subjected to compression, the distribution of the compressive stress on any cross-section depends, first, upon whether the resultant of the pressure acts along the line containing the centres of gravity of the sections, and, secondly, upon the dimensions of the piece; thus determining whether it will bend or not.

In the case of an eccentric load, or of a piece of such length that it yields by bending, the stress is not uniformly distributed; and, in order to proportion the piece, we must determine the greatest intensity of the stress upon it, and so proportion it that this shall be kept within the working-strength of the material for compression.

Either of these cases is not a case of direct compression.

In the case of direct compression (i.e., where the stress over each section is uniformly distributed), the intensity of the stress is found by dividing the total compression by the area of the

section ; so that, if  $P$  be the total compression, and  $A$  the area of the section, and  $p$  the intensity of the compressive stress,

$$p = \frac{P}{A}.$$

On the other hand, if  $f$  is the compressive working-strength of the material per square inch, and  $A$  the area of the section in square inches, then the greatest allowable load on the piece subjected to compression is

$$P = fA.$$

The same remarks as were made in regard to a suddenly applied load and resilience, in the case of direct tension, apply in the case of direct compression.

**§ 176. Results of Wöhler's Experiments on Compressive Strength.** — Wöhler also made experiments in regard to pieces subjected to alternate tension and compression, taking, in the experiments themselves, the case where the metal is subjected to alternate tensions and compressions of equal amount.

The greatest stress of which the piece would bear an indefinite number of changes under these conditions, is called the vibration safe strength, and is denoted by  $s$ .

Weyrauch deduces a formula similar to that of Launhardt for the greatest allowable stress per unit of area on the piece when it is subjected to alternate tensions and compressions of different amounts.

Thus, for Phoenix Company's axle iron, Wöhler deduces

$$\begin{aligned} t &= 3290 \text{ kil. per sq. cent.} = 46800 \text{ lbs. per sq. in.,} \\ u &= 2100 \text{ kil. per sq. cent.} = 30000 \text{ lbs. per sq. in.,} \\ s &= 1170 \text{ kil. per sq. cent.} = 16600 \text{ lbs. per sq. in.} \end{aligned}$$

Weyrauch's formula for the ultimate strength per unit of area is

$$a = u \left\{ 1 - \frac{u - s}{u} \frac{\text{least maximum stress}}{\text{greatest maximum stress}} \right\};$$

and, with these values of  $u$  and  $s$ , it gives

$$a = 2100 \left\{ 1 - \frac{1}{2} \frac{\text{least maximum stress}}{\text{greatest maximum stress}} \right\} \text{ kil. per sq. cent.,}$$

or

$$a = 30000 \left\{ 1 - \frac{1}{2} \frac{\text{least maximum stress}}{\text{greatest maximum stress}} \right\} \text{ lbs. per sq. in.}$$

With a factor of safety of 3, we should have, for the greatest admissible stress per square inch,

$$b = 10000 \left\{ 1 - \frac{1}{2} \frac{\text{least maximum stress}}{\text{greatest maximum stress}} \right\} \text{ lbs.}$$

For Krupp's cast-steel,

$$t = 7340 \text{ kil. per sq. cent.} = 104400 \text{ lbs. per sq. in.,}$$

$$u = 3300 \text{ kil. per sq. cent.} = 46900 \text{ lbs. per sq. in. approximately,}$$

$$s = 2050 \text{ kil. per sq. cent.} = 29150 \text{ lbs. per sq. in. approximately.}$$

We have, therefore, for the breaking-strength per unit of area, according to Weyrauch's formula,

$$a = 3300 \left\{ 1 - \frac{5}{11} \frac{\text{least maximum stress}}{\text{greatest maximum stress}} \right\} \text{ kil. per sq. cent.,}$$

or

$$a = 46900 \left\{ 1 - \frac{5}{11} \frac{\text{least maximum stress}}{\text{greatest maximum stress}} \right\} \text{ lbs. per sq. in. ;}$$

and, using a factor of safety of 3, we have, for the greatest admissible stress per square inch,

$$\delta = 15630 \left\{ 1 - \frac{5}{11} \frac{\text{least maximum stress}}{\text{greatest maximum stress}} \right\} \text{ lbs. per sq. in.}$$

The principles respecting an eccentric compressive load, and those respecting the giving-way of long columns so far as they are known, can only be treated after we have studied the resistance of beams to bending; hence this subject will be deferred until that time.

#### EXAMPLES.

Find the proper working and breaking strength per square inch to be used for a wrought-iron rod, the extreme stresses being—

1. 80000 lbs. tension and 6000 lbs. compression.
2. 100000 lbs. tension and 100000 lbs. compression.
3. 70000 lbs. tension and 60000 lbs. compression.

Do the same for a steel rod.

§ 177. **Resistance to Shearing.**— One of the principal cases where the resistance to shearing comes into practical use is that where the members of a structure, which are themselves subjected to direct tension or compression or bending, are united by such pieces as bolts, rivets, pins, or keys, which are subjected to shearing. Sometimes the shearing is combined with tension or with bending; and whenever this is the case, it is necessary to take account of this fact in designing the pieces. It is important that the pins, keys, etc., should be equally strong with the pieces they connect.

Probably one of the most important modes of connection is by means of rivets. In order that there may be only a shearing action, without any bending of the rivets, the latter must fit very tightly. The manner in which the riveting is done will necessarily affect very essentially the strength of the joints;

hence the only way to discuss fully the strength of riveted joints is to take into account the manner of effecting the riveting, and hence the results of experiments. These will be spoken of later; but the ordinary theories by which the strength and proportions of riveted joints are determined will be given, which theories are necessary also in discussing the results of experiments thereon.

The principle on which the theory is based is that of making the resistance of the joint to yielding equal in all the ways in which it is possible for it to yield.

A single-riveted lap-joint is one with a single row of rivets, as shown in Fig. 154.

FIG. 154.

A single-riveted butt-joint with one covering plate is shown in Fig. 155.

FIG. 155.

A single-riveted butt-joint with two covering plates is shown in Fig. 156.

FIG. 156.

FIG. 157.

A double-riveted lap-joint with the rivets staggered is shown in Fig. 157; one with chain riveting, in Fig. 158.

FIG. 158.

Taking the case of the single-riveted lap-joint shown in Fig. 154, it may yield in one of four ways :—

FIG. 159.

1°. By the crushing of the plate in front of the rivet (Fig. 159).

FIG. 160.

2°. By the shearing of the rivet (Fig. 160).

3°. By the tearing of the plate between the rivet-holes (Fig. 161).

FIG. 161.

4°. By the rivet breaking through the plate (Fig. 162).

FIG. 162.

Let us call

$d$  the diameter of a rivet.

$c$  the pitch of the rivets; i.e., their distance apart from centre to centre.

$t$  the thickness of the plate.

$l$  the lap of the plate; i.e., the distance from the outer edge of a rivet-hole to the outer edge of the plate.

$f_t$  the ultimate tensile strength of the iron.

$f_s$  the ultimate shearing-strength of the rivet iron.

$f_c$  the ultimate crushing-strength of the iron.

We shall then have —

1°. Resistance of plate in front of rivet to crushing  $= f_c t d$ .

2°. Resistance of one rivet to shearing  $= f_s \left( \frac{\pi d^2}{4} \right)$ .

3°. Resistance of plate between two rivet-holes to tearing  $= f_t (c - d)$ .

4° Resistance of plate to being broken through  $= a \frac{t l^2}{d}$ , where

$a$  is a constant depending on the material. This may be taken as empirical for the present.

An average value of this constant, as given by Robert Wilson, is 100000 lbs., where all the dimensions are measured in

inches. Assuming that we know the thickness of the plate to start with, we obtain, by equating the first two resistances,

$$f_c t d = f_s \frac{\pi d^2}{4} \quad \therefore d = \frac{4t}{\pi} \frac{f_c}{f_s},$$

which determines the diameter of the rivet.

Equating 3° and 2°, we obtain

$$f_t t (c - d) = f_s \frac{\pi d^2}{4} \quad \therefore c = d + \frac{f_s}{f_t} \frac{\pi d^2}{4t},$$

which gives the pitch of the rivets in terms of the diameter of the rivet, and the thickness of the plate.

Equating, next, 4° and 1°, we have

$$a \frac{t^2}{d} = f_c t d \quad \therefore l = d \sqrt{\frac{f_c}{a}},$$

which gives the lap of the plate.

A similar method of reasoning would enable us to determine the corresponding quantities in the cases of double-riveted joints, etc.

The above is the ordinary theory of riveted joints: it assumes that the joint should be made equally strong against giving way by any method in which it is possible for it to give way. There are a number of practical considerations which modify more or less the results of this theory, and which can only be determined experimentally. A fuller account of this subject from an experimental point of view will be given later.

§ 178. **Intensity of Stress.**—Whenever the stress over a plane area is uniformly distributed, we obtain its intensity at each point by dividing the total stress by the area over which it acts, thus obtaining the amount per unit of area. When, however, the stress is not uniformly distributed, or when its inten-

sity varies at different points, we must adopt a somewhat different definition of its *intensity at a given point*. In that case, if we assume a small area containing that point, and divide the stress which acts on that area by the area, we shall have, in the quotient, an approximation to the intensity required, which will approach nearer and nearer to the true value of the intensity at that point, the smaller the area is taken.

Hence the intensity of a variable stress at a given point is, —

*The limit of the ratio of the stress acting on a small area containing that point, to the area, as the latter grows smaller and smaller.*

By dividing the total stress acting on a certain area by the entire area, we obtain the mean intensity of the stress for the entire area.

§ 179. **Graphical Representation of Stress.** — A convenient mode of representing stress graphically is the following:—

Let  $AB$  (Fig. 163) be the plane surface upon which the stress acts; let the axes  $OX$  and  $OY$  be taken in this plane, the axis  $OZ$  being at right angles to the plane.

Conceive a portion of a cylinder whose elements are all parallel to  $OZ$ , bounded at one end by the given plane surface, and at the other by a surface whose ordinate at any point contains as many units of length as there are units of force in the intensity of the stress at that point of the given plane surface where the ordinate cuts it.

The volume of such a figure will evidently be

$$V = \iint z dx dy = \iint p dx dy,$$

where  $z = p$  = intensity of the stress at the given point.

FIG. 163.

Hence the volume of the cylindrical figure will contain as many units of volume as the total stress contains units of force; or, in other words, the total stress will be correctly represented by the volume of the body.

FIG. 164.

If the stress on the plane figure is partly tension and partly compression, the surface whose ordinates represent the intensity of the stress will lie partly on one side of the given plane surface and partly on the other; this surface and the plane surface on which the stress acts, cutting each other in some line, straight or curved, as shown in Fig. 164. In that

case, the magnitude of the resultant stress  $P = V = \iiint z \, dx \, dy$  will be equal to the difference of the wedge-shaped volumes shown in the figure.

It will be observed that the above method of representing stress graphically represents, 1°, the intensity at each point of the surface to which it is applied; and, 2°, the total amount of the stress on the surface. It does not, however, represent its direction, except in the case when the stress is normal to the surface on which it acts.

In this latter case, however, this is a complete representation of the stress.

The two most common uses of stress are, 1°, uniform stress, and, 2°, uniformly varying stress. These two cases are represented respectively in Figs. 165 and 166; the direction also being correctly represented when, as is most frequently the case, the stress is normal to the surface of action. In Fig. 165,  $AB$  is supposed to be the surface on which the stress

acts; the stress is supposed to be uniform, and normal to the surface on which it acts; the bounding surface in this case becomes a plane parallel to  $AB$ ; the intensity of the stress at any point, as  $P$ , will be represented by  $PQ$ ; while the whole cylinder will contain as many units of volume as there are units of force in the whole stress.

Fig. 166 represents a uniformly varying stress. Here, again,  $AB$  is the surface of action, and the stress is supposed to vary at a uniform rate from the axis  $OY$ .

FIG. 166.

The upper bounding surface of the cylindrical figure which represents the stress becomes a plane inclined to the  $XOY$  plane, and containing the axis  $OY$ .

In this case, if  $a$  represent the intensity of the stress at a unit's distance from  $OY$ , the stress at a distance  $x$  from  $OY$  will be  $p = ax$ , and the total amount of the stress will be

$$P = \iint p \, dx \, dy = a \iint x \, dx \, dy.$$

When a stress is oblique to the surface of action, it may be represented correctly in all particulars, except in direction, in the above-stated way.

§ 180. **Centre of Stress.**—The centre of stress, or the point of the surface at which the resultant of the stress acts, often becomes a matter of practical importance. If, for convenience, we employ a system of rectangular co-ordinate axes, of which the axes  $OX$  and  $OY$  are taken in the plane of the surface on which the stress acts, and if we let  $p = \phi(x, y)$  be

FIG. 165.

the intensity of the stress at the point  $(x, y)$ , we shall have, for the co-ordinates of the centre of stress,

$$x_1 = \frac{\iint x p dx dy}{\iint p dx dy}, \quad y_1 = \frac{\iint y p dx dy}{\iint p dx dy},$$

(see § 42), where the denominator, or  $\iint p dx dy$ , represents the total amount of the stress.

When the stress is positive and negative at different parts of the surface, as in Fig. 135, the case may arise when the positive and negative parts balance each other, and hence the stress on the surface constitutes a statical couple. In that case

$$\iint p dx dy = 0.$$

§ 181. **Uniform Stress.** — In the case of uniform stress, we have —

1°. The intensity of the stress is constant, or  $p =$  a constant.

2°. The volume which represents it graphically becomes a cylinder with parallel and equal bases, as in Fig. 165.

3°. The centre of stress is at the centre of gravity of the surface of action; for the formulæ become, when  $p$  is constant,

$$x_1 = \frac{p \iint x dx dy}{p \iint dx dy} = \frac{\iint x dx dy}{\iint dx dy} = x_0,$$

$$y_1 = \frac{p \iint y dx dy}{p \iint dx dy} = \frac{\iint y dx dy}{\iint dx dy} = y_0,$$

where  $x_0, y_0$  are the co-ordinates of the centre of gravity of the surface.

Examples of uniform stress have already been given in the cases of direct tension, direct compression, and, in the case of riveted joints, for the shearing-force on the rivet.

§ 182. **Uniformly Varying Stress.** — Uniformly varying stress has already been defined as a stress whose intensity varies uniformly from a given line in its own plane; and this line will be called the *Neutral Axis*. Thus, if the plane be taken as the  $XOY$  plane (Fig. 166), and the given line be taken as  $OY$ , we shall have, if  $a$  denotes the intensity of the stress at a unit's distance from  $OY$ , and  $x$  the distance of any special point from  $OY$ , that the intensity of the stress at the point will be

$$p = ax.$$

The total amount of the stress will be

$$P = a \iint x dx dy.$$

The total moment of the stress about  $OY$  will be found by multiplying each elementary stress by its leverage. This leverage is, in the case of normal stress,  $x$ ; hence in that case the moment of any single elementary force will be

$$(ax \Delta x \Delta y)x = ax^2 \Delta x \Delta y,$$

and the total moment of the stress will be

$$M = a \iint x^2 dx dy.$$

In the case of oblique stress, this result has to be modified, as the leverage is no longer  $x$ . Confining ourselves to stress normal to the plane of action, we have, for the co-ordinates of the centre of stress,

$$x_1 = \frac{\iint p x dx dy}{\iint p dx dy} = \frac{a \iint x^2 dx dy}{P} = \frac{\iint x^2 dx dy}{\iint x dx dy} = \frac{\iint x^2 dx dy}{x_o A},$$

$$y_1 = \frac{\iint p y dx dy}{\iint p dx dy} = \frac{a \iint x y dx dy}{P} = \frac{\iint x y dx dy}{\iint x dx dy} = \frac{\iint x y dx dy}{x_o A},$$

since

$$P = a \iint x dx dy = ax_o A,$$

where  $x_o, y_o$  are the co-ordinates of the centre of gravity, and  $A$  is the area of the surface of action.

§ 183. **Case of a Uniformly Varying Stress which amounts to a Statical Couple.**—Whenever  $P = 0$ , we have

$$a \iint x dx dy = 0 \quad \therefore \iint x dx dy = 0 \quad \therefore x_o A = 0 \quad \therefore x_o = 0.$$

In this case, therefore, we have —

1°. There is no resultant stress, and hence the whole stress amounts to a statical couple.

2°. Since  $x_o = 0$ , the centre of gravity of the surface of action is on the axis  $OY$ , which is the neutral axis.

Hence follows the proposition:—

*When a uniformly varying stress amounts to a statical couple, the neutral axis contains (passes through) the centre of gravity of the surface of action.*

In this case there is no single resultant of the stress; but the moment of the couple will be, as has been already shown,

$$M = a \iint x^2 dx dy.$$

§ 184. **Example of Uniformly Varying Stress.**—One of the most common examples of uniformly varying stress is that of the pressure of water upon the sides of the vessel containing it.

Thus, let Fig. 167 represent the vertical cross-section of a reservoir wall, the water pressing against the vertical face  $AB$ . It is a fact established by experiment, that the intensity of the pressure of any body of water at any point is proportional to the depth of the point below the free upper level of the water, and normal to the surface pressed upon. Hence, if we suppose the free upper level of the water to be even with the top of the wall, the intensity of the pressure there will be zero; and if we represent by  $CB$  the intensity of the pressure at the bottom, then, joining  $A$  and

FIG. 167.

$C$  we shall have the intensity of the pressure at any point, as  $D$ , represented by  $ED$ , where

$$ED : CB = AD : AB.$$

Here, then, we have a case of uniformly varying stress normal to the surface on which it acts.

§ 185. **Fundamental Principles of the Common Theory of the Stresses in Beams under a Transverse Load.** — Fig. 168

shows a beam fixed at one end and loaded at the other, while Fig. 169 shows a beam supported at the ends and loaded at the middle. Let, in each case, the plane of the paper contain a vertical longitudinal section of the beam. In

FIG. 168.

Fig. 168, it is evident that the upper fibres are lengthened, while the lower ones are shortened, and *vice versa* in Fig. 169. In either case, there is, somewhere between the upper and lower fibres, a fibre which is neither elongated nor compressed.

FIG. 169.

Let  $CN$  represent that fibre, Fig. 168, and  $CP$ , Fig. 169. This line may be called the neutral line of the longitudinal section; and, if a section be made at any point at right

angles to this line, the horizontal line which lies in the cross-section, and cuts the neutral lines of all the longitudinal sections, or, in other words, the locus of the points where the neutral lines of the longitudinal sections cut the cross-section, is called the *Neutral Axis* of the cross-section. In the ordinary theory of the stresses in beams, a number of assumptions are made, which will now be enumerated.

#### ASSUMPTIONS MADE IN THE COMMON THEORY OF BEAMS.

**ASSUMPTION No. 1.** — If, when a beam is not loaded, a plane cross-section be made, this cross-section will still be a plane after the load is put on, and bending takes place. From this assumption, we deduce, as a consequence, that, if a certain cross-section be assumed, the elongation or shortening per unit of length of any fibre at the point where it cuts this cross-section, is proportional to the distance of the fibre from the neutral axis of the cross-section.

*Proof.* — Imagine two originally parallel cross-sections so near to each other that the curve in which that part of the neutral line between them bends may, without appreciable error, be accounted circular. Let  $ED$  and  $GH$  (Fig. 168 or Fig. 169) be the lines in which these cross-sections cut the plane of the paper, and let  $O$  be the point of intersection of the lines  $ED$  and  $GH$ . Let  $OF = r$ ,  $FL = y$ ,  $FK = l$ ,  $LM = l + \alpha l$ , in which  $\alpha$  is the strain or elongation per unit of length of a fibre at a distance  $y$  from the neutral line,  $y$  being a variable; then, because  $FK$  and  $LM$  are concentric arcs subtending the same angle at the centre, we shall have the proportion

$$\frac{r + y}{r} = \frac{l + \alpha l}{l} \quad \text{or} \quad 1 + \alpha = 1 + \frac{y}{r}$$

$$\therefore \alpha = \frac{y}{r} \quad \text{or} \quad \alpha = \left(\frac{1}{r}\right)y;$$

but as  $y$  varies for different points in any given cross-section, while  $r$  remains the same for the same section, it follows, that, if a certain cross-section be assumed, *the strain of any fibre at the point where it cuts this cross-section is proportional directly to the distance of this fibre from the neutral axis of the cross-section.*

ASSUMPTION No. 2. — This assumption is that commonly known as *Hooke's Law*. It is as follows: "*Ut tensio sic vis*;" i.e., The stress is proportional to the strain, or to the elongation or compression per unit of length. As to the evidence in favor of this law, experiment shows, that, as long as the material is not strained beyond safe limits, this law holds. Hence, making these two assumptions, we shall have: *At a given cross-section of a loaded beam, the direct stress on any fibre varies directly as the distance of the fibre from the neutral axis.* Hence it is a uniformly varying stress, and we may represent it graphically as follows: Let  $ABCD$ , Fig. 170, be the cross-section of a beam, and  $KL$  the neutral axis. Assume this for axis  $OY$ , and draw the other two axes, as in the figure. If, now,  $EA$  be drawn to represent the intensity of the direct (normal) stress at  $A$ , then will the pair of wedges  $AEFBKL$  and  $DCHGKL$  represent the stress graphically, since it is uniformly varying.

FIG. 170.

#### POSITION OF NEUTRAL AXIS.

ASSUMPTION No. 3. — It will next be shown, that, on the two assumptions made above, and from the further assumption that the only resistances opposed to the bending of the beam

are the direct tensions and compressions of the fibres, it follows that the neutral axis must pass through the centre of gravity of the cross-section.

FIG. 171.

FIG. 172.

Since the curvatures in Figs. 168 and 169 are exaggerated in order to render them visible, Figs. 171 and 172 have been drawn. If, now, we assume a section  $DE$ , such that  $AD = x$  (Fig. 171) and  $NE = x$  (Fig. 172), and consider all the forces acting on that part of the beam which lies to the right of  $DE$  (i.e., both the external forces and the stresses which the other parts of the beam exert on this part), we must find them in equilibrium. The external forces are, in Fig. 172, —

1°. The loads acting between  $B$  and  $E$ ; in this case there are none.

2°. The supporting force at  $B$ ; in this case it is equal to  $\frac{W}{2}$ , and acts vertically upwards.

In Fig. 143 they are, —

The loads between  $D$  and  $N$ ; in this case there is only the one,  $W$  at  $N$ .

The internal forces are merely the stresses exerted by the other parts of the beam on this part: they are, —

1°. The resistance to shearing at the section, which is a vertical stress.

2°. The direct stresses, which are horizontal.

Now, since the part of the beam to the right of  $DE$  is at rest, the forces acting on it must be in equilibrium; and, since

they are all parallel to the plane of the paper, we must have the three following conditions ; viz., —

- 1°. The algebraic sum of the vertical forces must be zero.
- 2°. The algebraic sum of the horizontal forces must be zero.
- 3°. The algebraic sum of the moments of the forces about any axis perpendicular to the plane of the paper must be zero.

But, on the above assumptions, the only horizontal forces are the direct stresses : hence the algebraic sum of these direct stresses must be zero ; or, in other words, the direct stresses must be equivalent to a statical couple.

Now, it has already been shown, that, whenever a uniformly varying stress amounts to a statical couple, the neutral axis must pass through the centre of gravity of the surface acted upon. Hence in a loaded beam, if the three preceding assumptions be made, it follows that the neutral axis of any cross-section must contain the centre of gravity of that section.

By way of experimental proof of this conclusion, Barlow has shown by experiment, that, in a cast-iron beam of rectangular section, the neutral axis does pass through the centre of gravity of the section.

#### RÉSUMÉ.

The conclusions arrived at from the foregoing are as follows :—

1°. That at any section of a loaded beam, if a horizontal line be drawn through the centre of gravity of the section, then the fibres lying along this line will be subjected neither to tension nor to compression ; in other words, this line will be the neutral axis of the section.

2°. The fibres on one side of this line will be subjected to tension, those on the other side being subjected to compression ; the tension or compression of any one fibre being proportional to its distance from the neutral axis.

§ 186. **Shearing-Force and Bending-Moment.** — In determining the strength of a beam, or the proper dimensions of a beam to bear a certain load, when we assume the neutral axis to pass through the centre of gravity of the cross-section, we have imposed the second of the three last-mentioned conditions of equilibrium. The remaining two conditions may otherwise be stated as follows : —

1°. The total force tending to cause that part of the beam that lies to one side of the section to slide by the other part, must be balanced by the resistance of the beam to shearing at the section.

2°. The resultant moment of the external forces acting on that part of the beam that lies to one side of the section, about a horizontal axis in the plane of the section, must be balanced by the moment of the couple formed by the resisting stresses.

*The shearing-force at any section is the force with which the part of the beam on one side of the section tends to slide by the part on the other side.* In a beam free at one end, it is equal to the sum of the loads between the section and the free end. In a beam supported at both ends, it is equal in magnitude to the difference between the supporting force at either end, and the sum of the loads between the section and that support.

The bending-moment at any section is the resultant moment of the external forces acting on the part of the beam to one side of the section, these moments being taken about a horizontal axis in the section.

In a beam free at one end, it is equal to the sum of the moments of the loads between the section and the free end, about a horizontal axis in the section.

In a beam supported at both ends, it is the difference between the moment of either supporting force, and the sum of the moments of the loads between the section and that support ; all the moments being taken about a horizontal axis in the section.

Hence the two conditions of equilibrium may be more briefly stated as follows :—

1°. The shearing-force at the section must be balanced by the resistance opposed by the beam to shearing at the section.

2°. The bending-moment at the section must be balanced by the moment of the couple formed by the resisting stresses.

It is necessary, therefore, in determining the strength of a beam, to be able to determine the shearing-force and bending-moment at any point, and also the greatest shearing-force and the greatest bending-moment, whatever be the loads.

A table of these values for a number of ordinary cases will now be given ; but I should recommend that the table be merely considered as a set of examples, and that the rules already given for finding them be followed in each individual case.

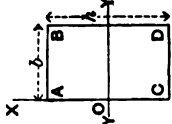

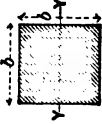

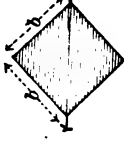

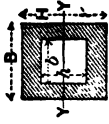

Let, in each case, the length of the beam be  $l$ , and the total load  $W$ . When the beam is fixed at one end and free at the other, let the origin be taken at the fixed end ; when it is supported at both ends, let it be taken directly over one support. Let  $x$  be the distance of any section from the origin. Then we shall have the results given in the following table :—

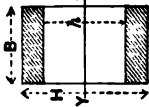

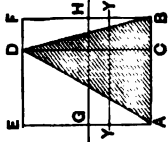

| Description of Beam.                         | Distribution of the Load.                               | Shearing Force.                          |  | Bending-Moment.                                |                                  |
|--|---|--|--|--|----------------------------------|
|  |   | At Distance $x$ from Origin.             | Greatest.                                | At Distance $x$ from Origin.                   | Greatest.                        |
| Beam fixed at one end,<br>free at the other, | Single load at free end,<br>Load uniformly distributed, | $W$<br>$\frac{W}{l}(l-x)$                | $W$<br>$W$                               | $Wl(l-x)$<br>$\frac{W}{2l}(l-x)^2$             | $Wl$<br>$\frac{Wl}{2}$           |
|  | Single load at middle,<br>Load uniformly distributed,   | $\frac{W}{2}$<br>$-\frac{W}{2}$          | $\frac{W}{2}$<br>$\frac{W}{2}$           | $\frac{W}{2}x$<br>$\frac{W}{2}(l-x)$           | $\frac{Wl}{4}$<br>$\frac{Wl}{8}$ |
| Beam supported at both ends,                 | Single load at distance $a$ from origin,                | $\frac{W(l-a)}{l}$<br>$\frac{W(l-a)}{l}$ | $\frac{W(l-a)}{l}$<br>$\frac{W(l-a)}{l}$ | $\frac{W(l-a)x}{l}$<br>$\frac{W(l-a)}{l}(l-x)$ | $\frac{Wl(l-a)}{l}$              |
|  | Single load at free end,<br>Load uniformly distributed, | $W$<br>$\frac{W}{l}(l-x)$                | $W$<br>$W$                               | $Wl(l-x)$<br>$\frac{W}{2l}(l-x)^2$             | $Wl$<br>$\frac{Wl}{2}$           |

In a beam fixed at one end and free at the other, the greatest shearing-force, and also the greatest bending-moment, are at the fixed end. In a beam supported at both ends, and loaded at the middle, or with a uniformly distributed load, the greatest shearing-force is at either support, the greatest bending-moment being at the middle. In the last case (i.e., that of a beam supported at the ends, and having a single load not at the middle), the greatest bending-moment is at the load; the greatest shearing-force being at that support where the supporting force is greatest.

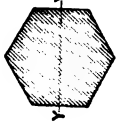

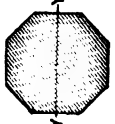

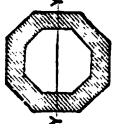

§ 187. **Moments of Inertia of Sections.** — In the usual methods of determining the strength of a beam or column, it is necessary to know, 1°, the distance from the neutral axis of the section to the most strained fibres; 2°, the moment of inertia of the section about the neutral axis. The manner of finding the moments of inertia has been explained in Chap. II.

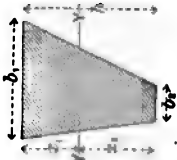

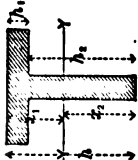

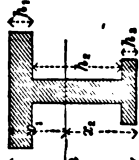

In the following table are given the areas of a large number of sections, and also their moments of inertia about the neutral axis, which is the axis *YY* in each case. These results should be deduced by the student.

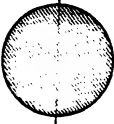

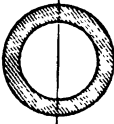

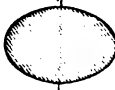

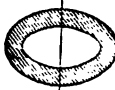

| Figure.  | Description.   | $A$ .     | $I$ .                       | Distance of $YY'$ from Most Strained Fibre. |

§ 189. **Graphical Representation of Bending-Moments.**—The bending-moment at each point of a loaded beam may be represented graphically by lines laid off to scale, as will be shown by examples.

I. Suppose we have the cantilever shown in Fig. 215, loaded at  $D$  with a load  $W$ : then will the bending-moment at any section, as at  $F$ , be obtained by multiplying  $W$  by  $FD$ ; that at  $AC$  being  $W \times (AB)$ . If, now, we lay off  $CE$  to scale to represent this, i.e., having as many units of length as there are units of moment in the product  $W \times (AB)$ , and join  $E$  with  $D$ , then will the ordinate  $FG$  of any point, as  $G$ , represent (to the same scale) the bending-moment at a section through  $F$ .

FIG. 215.

II. If we have a uniformly distributed load, we should have, for the line corresponding to  $CE$  in Fig. 215, a curve. This is

FIG. 216.

shown in Fig. 216, where we have the uniformly distributed load  $EIGF$ . If we take the origin at  $D$ , as before, we have, for the bending-moment, at a distance  $x$  from the origin, as has been shown,  $\frac{W}{2l}(l-x)^2$ ; and by giving  $x$  dif-

ferent values, and laying off the corresponding value of the bending-moment, we obtain the curve  $CA$ , any ordinate of which will represent the bending-moment at the corresponding point of the beam.

When we have more than one load on a beam, we must draw the curve of bending-moments for each load separately, and then find the actual bending-moment at any point of the beam

by taking the sum of the ordinates (drawn from that point) of each of these separate curves or straight lines. If we then draw a new curve, whose ordinates are these sums, we shall have the actual curve of bending-moments for the beam as loaded. Some examples will now be given, which will explain themselves.

III. Fig. 217 shows a cantilever with three concentrated loads. The line of bending-moments for the load at  $C$  is  $CE$ , that for the load at  $O$  is  $OF$ , and for the load at  $P$  is  $PG$ . They are combined above the beam by laying off  $AH = DE$ ,  $HK = DF$ , and  $KL = DG$ , and thus obtaining the broken line  $LMNB$ , which is the line of bending-moments of the beam loaded with all three loads.

FIG. 217.

IV. Fig. 218 shows the case of a beam supported at both ends, and loaded at a single point  $D$ ;  $ALB$  is the line of bending-moments when the weight of the beam is disregarded, so that  $xy =$  bending-moment at  $x$ .

FIG. 218.

V. Fig. 219 shows the case of a beam supported at the ends, and loaded with three concentrated loads at the points  $B$ ,  $C$ , and  $D$  respectively; the lines of bending-moments for each individual load being respectively  $AFE$ ,  $AGE$ , and  $AHE$ , and the actual line of bending-moments being  $AKLME$ .

FIG. 219.

VI. Fig. 220 shows the case of a beam supported at the ends, and loaded with a uniformly distributed load; the line of bending-moments being a curve,  $ACDB$ , as shown in the figure.

FIG. 220.

VII. In Fig. 221 we have the case of a beam, over a part of which, viz.,  $EF$ , there is a distributed load; the rest of the beam being unloaded. The line of bending-moments is curvilinear between  $E$  and  $F$ , and straight outside of these limits. It is  $AGSHB$ ; and, when the curve is plotted, we can find the greatest bending-moment

FIG. 221.

graphically by finding its greatest ordinate. We can also determine it analytically by first determining the bending-moment at a distance  $x$  from the origin, and on the side towards the resultant of the load, and then differentiating. This process is shown in the following:—

Let  $A$  (Fig. 222) be the point where the resultant of the load acts, and  $O$  the middle of the beam, and let  $w$  be the load per unit of length; let  $OA = a$ , and  $AB = AC = b$ , so that the whole load  $= 2wb$ : therefore supporting force at  $D = 2wb \frac{a+c}{2c} = \frac{wb(a+c)}{c}$ .

FIG. 222.

If we take a section at a distance  $x$  from  $O$  to the right, we shall have, for the bending-moment at that section,

$$\frac{wb(a+c)}{c}(c-x) - \frac{w}{2}(a+b-x)^2 = \text{a maximum.}$$

Differentiate, and we have

$$\frac{-wb(a+c)}{c} + w(a+b-x) = 0 \quad \therefore x = \frac{a(c-b)}{c};$$

hence the greatest bending-moment will be

$$\begin{aligned} & \frac{wb(a+c)}{c} \left( c - \frac{a(c-b)}{c} \right) - \frac{w}{2} \left( a + b - a + \frac{ab}{c} \right)^2 \\ &= \frac{wb}{c^2} (a+c)(c^2 - ac + ab) - \frac{wb^2}{2c^2} (a^2 + 2ac + c^2) \\ &= \frac{wb}{2c^2} (a^2b - 2a^2c + 2c^3 - bc^2). \end{aligned}$$

IX. In Fig. 225 we have a beam supported at *A* and *B*, and loaded at *C* and *D* with equal weights; the lengths of *AC* and *BD* being equal. We have, consequently, between *A* and *B*, a uniform bending-moment; while on the left of *A* and on the right of *B* we have a varying bending-moment. The line of bending-moments is, in this case, *CabD*.

FIG. 225.

We may, in a similar way, derive curves of bending-moment for all cases of loading and supporting beams.

§ 190. **Mode of Procedure for Ascertaining the Stresses at Different Parts of a Beam when the Loads and the Dimensions are given.** — When the dimensions of a beam, the load and its distribution, and the manner of supporting are given, and it is desired to find the actual intensity of the stress on any particular fibre at any given cross-section, we must proceed as follows :—

1°. Find the actual bending-moment ( $M$ ) at that cross-section.

2°. Find the moment of inertia ( $I$ ) of the section about its neutral axis.

3°. Observe, that, from what has already been shown, the moment of the couple formed by the tensions and compressions is  $aI$ , where  $a$  = intensity of stress of a fibre whose distance from the neutral axis is unity, and that this moment must equal the bending-moment at the section in order to secure equilibrium. Hence we must have

$$aI = M.$$

Moreover, if  $p$  denote the (unknown) intensity of the stress of the fibre where the stress is desired, and if  $y$  denote the distance of this fibre from the neutral axis, we shall have

$$a = \frac{p}{y},$$

$$\therefore \frac{p}{y}I = M, \quad \therefore p = \frac{My}{I},$$

from which equation we can determine  $p$ .

#### EXAMPLES.

1. Given a beam 18 feet span, supported at both ends, and loaded uniformly (its own weight included) with 1000 lbs. per foot of length. The cross-section is a T, where area of flange = 3 square inches, area of web = 4 square inches, height = 10 inches. Find ( $a$ ) the

bending at 3 feet from one end; (*b*) the greatest bending-moment; (*c*) the greatest intensity of the tension at each of the above sections; (*d*) the greatest intensity of the compression at each of these sections.

2. Given an I-beam with equal flanges, area of each flange = 3 square inches, area of web = 3 square inches, height = 10 inches; the beam is 12 feet long, supported at the ends, and loaded uniformly (its own weight included) with a load of 2000 lbs. per foot of length. Find (*a*) the bending-moment at a section one foot from the end; (*b*) the greatest bending-moment; (*c*) the greatest intensity of the stress at each of the above cross-sections.

§ 191. **Mode of Procedure for Ascertaining the Dimensions of a Beam to bear a Certain Load, or the Load that a Beam of Given Dimensions and Material is Capable of Bearing.**—If we wish to determine the proper dimensions of the beam when the load and its distribution, as well as the manner of supporting, are given, so that it shall nowhere be strained beyond safe limits, or if we wish to determine the greatest load consistent with safety when the other quantities are given, we must impose the condition that the greatest intensity of the tension to which any fibre is subjected shall not exceed the safe working-strength for tension of the material of which the beam is made, and the greatest intensity of the compression to which any fibre is subjected shall not exceed the safe working-strength of the material for compression.

Thus, we must in this case first determine where is the section of greatest bending-moment (this determination sometimes involves the use of the Differential Calculus).

Next we must determine the magnitude of the greatest bending-moment, absolutely if the load and length of the beam are given (if not, in terms of these quantities), and then equate this to the moment of the resisting couple.

Thus, if  $M_0$  is the greatest bending-moment,  $I_0$  the moment of inertia of that section where this greatest bending-moment

acts, and if  $f_t$  = working-strength per square inch for tension,  $f_c$  = working-strength per square inch for compression,  $y_t$  = distance of most stretched fibre from the neutral axis, and  $y_c$  = distance of most compressed fibre from the neutral axis, then will  $\frac{f_t}{y_t}$  be the greatest tension per square inch, at a unit's distance from the neutral axis, consistent with safety against tearing, and  $\frac{f_c}{y_c}$  the greatest compression per square inch, at a unit's distance from the neutral axis, consistent with safety against crushing.

Of course the least of these must not be exceeded in the actual beam. Hence we must put

$$M_o = \frac{f}{y} I,$$

where  $\frac{f}{y}$  is taken as the lesser of the two quantities  $\frac{f_t}{y_t}$  and  $\frac{f_c}{y_c}$ .

#### MODULUS OF RUPTURE.

The modulus of rupture is the greatest tension or compression per square inch to which the most strained fibre of the beam is subjected when the beam is just on the point of breaking.

#### WORKING-STRENGTH.

The working-strength per square inch of a material for transverse strength is the greatest stress per square inch to which it is safe to subject the most strained fibre of the beam. It is usually obtained by dividing the modulus of rupture by some factor of safety, as 3 or 4.

## § 192.

## EXAMPLES.

1. Given, as the modulus of rupture of a spruce beam, 4000 lbs. per square inch : find its breaking-strength, assuming it to be 4 inches wide and 12 inches deep, the span being 18 feet, the load being uniformly distributed over its entire length.

2. Suppose such a beam to break with a load at the middle of 5000 lbs. : find its modulus of rupture.

3. Given a T-beam fixed at one end, and loaded uniformly. The area of the flange is 3 square inches, that of the web also 3 square inches, height = 10 inches. The beam is 4 feet long. Find the greatest load it will bear with safety, the working-strength per square inch of the material being, for tension, 10000 lbs., and for compression 8000 lbs.

4. Given an I-beam, area of each flange being 3 square inches, and area of web 3 square inches, height = 12 inches, span 8 feet, supported at the ends, and loaded uniformly : what load will it bear with safety, the working-strength of the iron for tension, and also for compression, being 12000 lbs. per square inch.

5. Given a beam (Fig. 226) supported at both ends, and loaded,  $1^\circ$ , with  $w$  pounds per unit of length uniformly, and  $2^\circ$ , with a single load  $W$  at a distance  $a$  from the left-hand support : find the position of the section of greatest bending-moment, and the value of the greatest bending-moment.

*Solution.*

FIG. 226.

1. Left-hand supporting-force

$$= \frac{wl}{2} + \frac{W(l-a)}{l}.$$

Right-hand supporting-force

$$= \frac{wl}{2} + \frac{Wa}{l}.$$

2. Assume a section at a distance  $x$  from the left-hand support (this support being the origin), and the bending-moment at that section is, —

when  $x < a$ ,

$$\left\{ \frac{wl}{2} + \frac{W(l-a)}{l} \right\} x - \frac{wx^2}{2};$$

and when  $x > a$ ,

$$\left\{ \frac{wl}{2} + \frac{W(l-a)}{l} \right\} x - \frac{wx^2}{2} - W(x-a).$$

To find the value of  $x$  for the section of greatest bending-moment, differentiate each, and put the first differential co-efficient = zero.

We shall thus have, in the first case,

$$\frac{wl}{2} + \frac{W(l-a)}{l} - wx = 0, \text{ or } x = \frac{l}{2} + \frac{W(l-a)}{wl};$$

and in the second case,

$$\frac{wl}{2} + \frac{W(l-a)}{l} - wx - W = 0, \text{ or } x = \frac{l}{2} + \frac{W(l-a)}{wl} - \frac{W}{w}.$$

Now, whenever the first is  $< a$ , or the second is  $> a$ , we shall have in that one the value of  $x$  corresponding to the section of greatest bending-moment. But if the first is  $> a$ , and the second  $< a$ , then the greatest bending-moment is at the concentrated load.

These conclusions will be evident on drawing a diagram representing the bending-moments graphically, as in Figs. 223 and 224; and the greatest bending-moment may then be found by substituting, in the corresponding expression for the bending-moment, the deduced value of  $x$ .

6. Given an I-beam 10 feet long, supported at both ends, and loaded, at a distance 2 feet to the left of the middle, with 20000 pounds. Find the bending-moment at the middle, the greatest bending-moment, also the greatest intensity of the tension, and that of the compression at each of these sections.

Given Area of upper flange = 8 sq. in.

Area of lower flange = 5 sq. in.

Area of web = 7 sq. in.

Total depth = 14 in.

7. Given a beam (Fig. 227) 18 feet long, loaded at *A* with 1000 lbs., and at *B* with 2000 lbs.; the beam weighing 200 lbs. (*OA* = 3 feet, *OB* = 10 feet). Find the section of greatest bending-moment, and the bending-moment at that section.

FIG. 227.

§ 193. **Beams of Uniform Strength.**—A beam of uniform strength (technically so called) is one in which the dimensions of the cross-section are varied in such a manner, that, at each cross-section, the greatest intensity of the tension shall be the same, and so also the greatest intensity of the compression.

Such beams are very rarely used; and, as the cross-section varies at different points, it would be decidedly bad engineering to make them of wood, for it would be necessary to cut the wood across the grain, and this would develop a tendency to split.

In making them of iron, also, the saving of iron would generally be more than offset by the extra cost of rolling such a beam. Nevertheless, we will discuss the form of such beams in the case when the section is rectangular.

In all cases we have the general equation

$$M = \frac{\rho}{y} I$$

applying at each cross-section, where  $M$  = bending-moment (section at distance  $x$  from origin),  $I$  = moment of inertia of same section,  $y$  = distance from neutral axis to most strained fibre, and  $\rho$  = intensity of stress on most strained fibre; the condition for this case being that  $\rho$  is a constant for all values of  $x$  (i.e., for all positions of the section), while  $M$ ,  $I$ , and  $y$  are functions of  $x$ .

As we are limiting ourselves to rectangular sections, if we let  $b$  = breadth and  $h$  = depth of rectangle (one or both varying with  $x$ ), we shall have

$$M = \frac{p}{6} b h^3$$

as the condition for such a beam, with  $p$  a constant for all values of  $x$ , when the same load remains on the beam.

We must, therefore, have  $b h^3$  proportional to  $M$ . Hence, assuming the origin as before,

$$1^\circ. \text{ Fixed at one end, load at the other, } b h^3 = \left(\frac{6}{p}\right) W(l - x).$$

$$2^\circ. \text{ Fixed at one end, uniformly loaded, } b h^3 = \left(\frac{6}{p} \frac{W}{2l}\right) (l - x)^2.$$

$$3^\circ. \text{ Supported at ends, loaded at } \begin{cases} \text{for } x < \frac{l}{2}, b h^3 = \left(\frac{6}{p} \frac{W}{2}\right) x; \\ \text{middle,} \\ \text{for } x > \frac{l}{2}, b h^3 = \left(\frac{6}{p} \frac{W}{2}\right) (l - x). \end{cases}$$

$$4^\circ. \text{ Supported at ends, uniformly loaded, } b h^3 = \left(\frac{6}{p} \frac{W}{2l}\right) (lx - x^2).$$

Now, this variation of section may be accomplished in one of two ways: 1st, by making  $h$  constant, and letting  $b$  vary; and 2d, by making  $b$  constant, and letting  $h$  vary. Thus, in the first case above mentioned, if  $h$  is constant, we have, for the plan of the beam,

$$b = \left(\frac{6W}{p h^3}\right) (l - x):$$

and if one side be taken parallel to the axis of the beam, this will be the equation of the other side; and, as this is the equation of a straight line, the plan will be a triangle.

If, on the other hand,  $b$  be constant, and  $h$  vary, we shall have, for the vertical longitudinal section of the beam,

$$h^3 = \left( \frac{6W}{pb} \right) (l - x);$$

and, if one side be taken as a straight line in the direction of the axis, the other will be a parabola.

A similar reasoning will give the plan or elevation respectively in each case; and these can be readily plotted from their equations.

#### CROSS-SECTION OF EQUAL STRENGTH.

A cross-section of equal strength (technically so called) is one so proportioned that the greatest intensity of the tension shall bear the same ratio to the breaking tensile strength of the material as the greatest intensity of the compression bears to the breaking compressive strength of the material. This is accomplished, as will be shown directly, by so arranging the form and dimensions of the section that the distance of the neutral axis from the most stretched fibre shall bear to its distance from the most compressed fibre the same ratio that the tensile bears to the compressive strength of the material.

Let  $f_c$  = breaking-strength per square inch for compression,

$f_t$  = breaking-strength per square inch for tension,

$y_c$  = distance of neutral axis from most compressed fibre,

$y_t$  = distance of neutral axis from most stretched fibre.

If  $p_c$  = actual greatest intensity of compression, and  $p_t$  = actual greatest intensity of tension, then, for a cross-section of equal strength, we must have, according to the definition,

$\frac{p_c}{p_t} = \frac{f_c}{f_t}$ ; but we have  $\frac{p_c}{y_c} = \frac{p_t}{y_t}$  = intensity of stress at a unit's

distance from the neutral axis. Hence, combining these two, we obtain

$$\frac{y_c}{y_t} = \frac{f_c}{f_t}$$

EXAMPLE.

Suppose we have  $f_c = 80000$  lbs. per square inch, and  $f_t = 20000$  lbs. per square inch. : find the proper proportion between the flange  $A$ , and the web  $A_s$  of a T-section whose depth is  $h$ .

§ 194. **Deflection of Beams.** — We have already seen (§ 185), that, in the case of a beam which is bent by a transverse load, we have

$$a = \frac{1}{r}(y),$$

where (having assumed a certain cross-section whose distance from the origin is  $x$ )  $a$  = the *strain* of a fibre whose distance from the neutral axis is  $y$ , and  $r$  = radius of curvature of the neutral lamina at the section in question. Hence follows the equation

$$\frac{1}{r} = \frac{a}{y};$$

but from the definition of  $E$ , the modulus of elasticity, we shall have

$$a = \frac{\rho}{E},$$

where  $\rho$  = intensity of the stress at a distance  $y$  from the neutral axis.

Hence it follows, assuming Hooke's law, that

$$\frac{1}{r} = \frac{\rho}{Ey} = \frac{1}{E} \frac{\rho}{y}$$

We have already seen, that, disregarding signs,  $M = \frac{\rho}{y} I$

(making, of course, the two assumptions already spoken of when this formula was deduced), where  $M$  = bending-moment at, and  $I$  = moment of inertia of, the section in question ; i.e., of that section whose distance from the origin is  $x$ . This gives  $\frac{p}{y} = -\frac{M}{I}$ , if, denoting tension by the + sign, and taking  $y$  positive upwards, we call  $M$  positive when it tends to cause tension on the lower, and compression on the upper, side ; these being the conventions in regard to signs which we shall adopt in future. Hence, by substitution, we have

$$\frac{1}{r} = \frac{p}{Ey} = -\frac{M}{EI} \quad (1)$$

Now, if we assume the axis of  $x$  coincident with the neutral line of the central longitudinal section of the beam, and the axis of  $v$  at right angles to this, and  $v$  positive upwards, no matter where the origin is taken, we shall always have, as is shown in the Differential Calculus,

$$\frac{1}{r} = \frac{-\frac{d^2v}{dx^2}}{\left(1 + \left(\frac{dv}{dx}\right)^2\right)^{\frac{3}{2}}}$$

Hence equation (1) becomes

$$\frac{\frac{d^2v}{dx^2}}{\left(1 + \left(\frac{dv}{dx}\right)^2\right)^{\frac{3}{2}}} = \frac{M}{EI}, \quad (2)$$

$M$  and  $I$  being functions of  $x$  : and, when we can integrate this equation, we can obtain  $v$  in terms of  $x$ , thus having the equation of the elastic curve of the neutral line ; and, by computing the value of  $v$  corresponding to any assumed value of  $x$ , we can obtain the deflection at that point of the beam.

The above equation (2) is, as a rule, too complicated to be integrated, except by approximation; and the approximation usually made is the following:—

Since in a beam not too heavily loaded, the slope, and consequently the tangent of the slope (or angle the neutral line makes with the horizontal at any point), is necessarily small, it follows that  $\frac{dv}{dx}$  is very small, and hence  $\left(\frac{dv}{dx}\right)^2$  is also very small, and  $1 + \left(\frac{dv}{dx}\right)^2$  is nearly equal to unity. Making this substitution, we obtain, in place of equation (2),

$$\frac{d^2v}{dx^2} = \frac{M}{EI}; \quad (3)$$

and this is the equation with which we always start in computing the slope and deflection of a loaded beam, or in finding the equation of the elastic line.

By one integration (suitably determining the arbitrary constant) we obtain the slope whose tangent is  $\frac{dv}{dx}$ , and by a second integration we obtain the deflection  $v$  at a distance  $x$  from the origin; and thus, by substituting any desired value for  $x$ , we can obtain the deflection at any point.

§ 195. **Ordinary Formulæ for Slope and Deflection.**—We may therefore write, if  $i$  is the circular measure of the slope at a distance  $x$  from the origin, since  $i = \tan i = \frac{dv}{dx}$  nearly,

$$\begin{aligned} \frac{d^2v}{dx^2} &= \frac{M}{EI}, \\ i &= \frac{dv}{dx} = \int \frac{M}{EI} dx, \\ v &= \int \int \frac{M}{EI} dx^2. \end{aligned}$$

In these equations, of course,  $E$  is taken as a constant,  $M$  must ALWAYS be expressed in terms of  $x$ , and so also must  $I$  whenever the section varies at different points. When, however, the section is uniform,  $I$  is constant, and the formulæ reduce to

$$i = \frac{1}{EI} \int M dx, \quad v = \frac{1}{EI} \int \int M dx^2.$$

§ 196. **Special Cases.** — 1°. Let us take a cantilever loaded with a single load at the free end. Assume the origin, as before, at the fixed end, and let the beam be one of uniform section. We then have  $M = -W(l - x)$ ,

$$\therefore i = -\frac{W}{EI} \int (l - x) dx = -\frac{W}{EI} \left( lx - \frac{x^2}{2} \right) + c.$$

To determine  $c$ , observe that when  $x = 0$ ,  $i = 0$ ;

$$\therefore c = 0 \quad \therefore i = -\frac{W}{EI} \left( lx - \frac{x^2}{2} \right) \quad (1)$$

is the slope at a distance  $x$  from the origin.

The deflection at the same point will be

$$v = \int i dx = -\frac{W}{EI} \int \left( lx - \frac{x^2}{2} \right) dx = -\frac{W}{EI} \left( \frac{lx^2}{2} - \frac{x^3}{6} \right) + c;$$

but when  $x = 0$ ,  $v = 0 \quad \therefore c = 0 \quad \therefore$  the deflection at a distance  $x$  from the origin will be

$$v = -\frac{W}{EI} \left( \frac{lx^2}{2} - \frac{x^3}{6} \right). \quad (2)$$

The equations (1) and (2) give us the means of finding the slope and deflection at any point of the beam.

To find the greatest slope and deflection, we have that both expressions are greatest when  $x = l$ . Hence, if  $i_0$  and  $v_0$  represent the greatest slope and deflection respectively,

$$i_0 = -\frac{Wl^2}{2EI}, \quad v_0 = -\frac{Wl^3}{3EI}.$$

2°. Next take the case of a beam supported at both ends and loaded uniformly, the load per unit of length being  $w$ .

Assume the origin at the left-hand end; then

$$M = \frac{wl}{2}x - \frac{wx^2}{2} = \frac{w}{2}(lx - x^2) \quad \text{and} \quad W = wl$$

$$\therefore i = \frac{w}{2EI} \int (lx - x^2) dx = \frac{w}{2EI} \left( \frac{lx^2}{2} - \frac{x^3}{3} \right) + c.$$

To determine  $c$ , we have that when  $x = \frac{l}{2}$ , then  $i = 0$ ;

$$\therefore 0 = \frac{w}{2EI} \left( \frac{l^3}{8} - \frac{l^3}{24} \right) + c \quad \therefore c = -\frac{wl^3}{24EI}$$

$$\therefore i = \frac{w}{2EI} \left( \frac{lx^2}{2} - \frac{x^3}{3} \right) - \frac{wl^3}{24EI} = \frac{w}{24EI} (6lx^2 - 4x^3 - l^3) \quad (1)$$

$$\begin{aligned} \therefore v = \int i dx &= \frac{w}{24EI} \int (6lx^2 - 4x^3 - l^3) dx \\ &= \frac{w}{24EI} (2lx^3 - x^4 - l^3x) + c. \end{aligned}$$

But when  $x = 0$ ,  $v = 0$ ;

$$\therefore c = 0$$

$$\therefore v = \frac{w}{24EI} (2lx^3 - x^4 - l^3x). \quad (2)$$

For the greatest slope, we have  $x = 0$ , or  $x = l$ ;

$$\therefore i_0 = \frac{wl^3}{24EI} = \frac{Wl^3}{24EI}.$$

For the greatest deflection,  $x = \frac{l}{2}$ ;

$$\therefore v_0 = \frac{w}{24EI} \frac{5l^4}{16} = \frac{5wl^4}{384EI} = \frac{5Wl^3}{384EI}.$$

3°. Take the case of a beam supported at both ends, and loaded at the middle with a load  $W$ .

Assume, as before, the origin at the left-hand support. Then we shall have

$$M = \frac{W}{2}x, \quad x < \frac{l}{2}, \quad \text{and} \quad M = \frac{W}{2}(l - x) \quad \text{when} \quad x > \frac{l}{2}$$

Therefore, for the slope up to the middle, we have

$$i = \frac{W}{2EI} \int x dx = \frac{W}{2EI} \frac{x^2}{2} + c.$$

When  $x = \frac{l}{2}$ , then  $i = 0$ ;

$$\therefore c = -\frac{Wl^2}{16EI}$$

$$\therefore i = \frac{W}{4EI} \left( x^2 - \frac{l^2}{4} \right), \quad (1)$$

and

$$v = \frac{W}{4EI} \int \left( x^2 - \frac{l^2}{4} \right) dx = \frac{W}{4EI} \left( \frac{x^3}{3} - \frac{l^2 x}{4} \right) + c.$$

But when  $x = 0$ ,  $v = 0$ ;

$$\therefore c = 0$$

$$\therefore v = \frac{W}{4EI} \left( \frac{x^3}{3} - \frac{l^2 x}{4} \right). \quad (2)$$

The slope is greatest when  $x = 0$ ;

$$\therefore i_0 = \frac{Wl^2}{16EI}.$$

The deflection is greatest when  $x = \frac{l}{2}$ ;

$$\therefore v_0 = \frac{Wl^3}{48EI}.$$

In this case the symmetry of the beam and load makes it

unnecessary to examine the part where  $x > \frac{l}{2}$ ; but, if this were to be done, we should have, for that part,

$$i = \frac{W}{2EI} \int (l-x) dx \quad \text{and} \quad v = \frac{W}{2EI} \int \int (l-x) dx^2.$$

4°. Following will be found a table of some deflections, which may be regarded as examples simply.

| Uniform Cross-Section.                          | Greatest Slope.                | Greatest Deflection.            |
|---|--------------------------------|---------------------------------|
| Fixed at one end, loaded at the other . . .     | $\frac{1}{2} \frac{Wl^2}{EI}$  | $\frac{1}{3} \frac{Wl^3}{EI}$   |
| Fixed at one end, loaded uniformly . . .        | $\frac{1}{6} \frac{Wl^2}{EI}$  | $\frac{1}{8} \frac{Wl^3}{EI}$   |
| Supported at ends, load at middle . . .         | $\frac{1}{16} \frac{Wl^2}{EI}$ | $\frac{1}{48} \frac{Wl^3}{EI}$  |
| Supported at ends, uniformly loaded . . .       | $\frac{2}{24} \frac{Wl^2}{EI}$ | $\frac{5}{384} \frac{Wl^3}{EI}$ |
| Uniform Strength and Uniform Depth.             |                                |                                 |
| Fixed at one end, load at the other . . .       | $\frac{Wl^2}{EI}$              | $\frac{1}{2} \frac{Wl^3}{EI}$   |
| Fixed at one end, uniformly loaded . . .        | $\frac{1}{2} \frac{Wl^2}{EI}$  | $\frac{1}{4} \frac{Wl^3}{EI}$   |
| Supported at both ends, load at middle . . .    | $\frac{1}{8} \frac{Wl^2}{EI}$  | $\frac{1}{32} \frac{Wl^3}{EI}$  |
| Supported at both ends, uniformly loaded, . . . | $\frac{1}{16} \frac{Wl^2}{EI}$ | $\frac{1}{64} \frac{Wl^3}{EI}$  |

§ 197. **Deflection with Uniform Bending-Moment.** — If the bending-moment is uniform, then  $M$  is constant; and, if  $I$  is also constant, we have

$$i = \frac{M}{EI} \int dx = \frac{Mx}{EI} + c;$$

but when  $x = \frac{l}{2}$ , then  $i = 0$ ;

$$\therefore c = -\frac{Ml}{2EI}$$

$$\therefore i = \frac{M}{EI} \left( x - \frac{l}{2} \right) = \frac{dv}{dx}$$

$$\therefore v = \frac{M}{EI} \left( \frac{x^2}{2} - \frac{lx}{2} \right),$$

the constant disappearing because  $v = 0$  when  $x = 0$ .

Hence, for a beam where the bending-moment is uniform, we have

$$i = \frac{M}{EI} \left( x - \frac{l}{2} \right), \quad v = \frac{M}{EI} \left( \frac{x^2}{2} - \frac{lx}{2} \right);$$

and for greatest slope and deflection, we have

$$i_0 = \frac{-Ml}{2EI}, \quad v_0 = \frac{M}{EI} \left( \frac{l^2}{8} - \frac{l^2}{2} \right) = -\frac{3Ml^2}{8EI}.$$

§ 198. **Resilience of a Beam.** — *The resilience of a beam is the mechanical work performed in deflecting it to the amount it would deflect under its greatest allowable gradually applied load.* In the case of a concentrated load, if  $W$  is the greatest allowable gradually applied load, and  $v$ , the corresponding deflection at the point of application of the load, then will the mean value of the load that produces this deflection be  $\frac{W}{2}$ , and the resilience of the beam will be  $\frac{W}{2}v$ .

§ 199. Slope and Deflection of a Beam with a Concentrated Load not at the Middle.—Take, as the next case, a beam (Fig. 228). Let the load at  $A$  be  $W$ , and distance  $OA = a$ , and let  $a > \frac{l}{2}$ .

$$x < a \quad M = \frac{W(l-a)}{l} x,$$

$$x < a \quad M = \frac{Wa}{l}(l-x),$$

$$\therefore x < a \quad i = \frac{W(l-a)}{lEI} \int x dx = \frac{W(l-a)}{2lEI} x^2 + c.$$

When  $x = 0$ ,  $i = i_0 =$  undetermined slope at  $O$ ;

$$\therefore c = i_0 \quad \therefore i = \frac{W(l-a)}{2lEI} x^2 + i_0 \quad (1)$$

and

$$\therefore v = \frac{W(l-a)}{2lEI} \int x^2 dx + i_0 \int dx = \frac{W(l-a)}{6lEI} x^3 + i_0 x + c.$$

When  $x = 0$ ,  $v = 0$ ;

$$\therefore v = \frac{W(l-a)}{6lEI} x^3 + i_0 x, \quad (2)$$

$$x > a \quad i = \frac{Wa}{lEI} \int (l-x) dx = \frac{Wa}{lEI} \left( lx - \frac{x^2}{2} \right) + c.$$

To determine  $c$ , observe that when  $x = a$ , this value of  $i$  and that deduced from (1) must be identical.

$$\frac{Wa}{lEI} \left( la - \frac{a^2}{2} \right) + c = \frac{W(l-a)a^2}{2lEI} + i_0 \quad \therefore c = -\frac{Wa^2}{2lEI} + i_0$$

$$\therefore i = \frac{Wa}{lEI} \left( lx - \frac{x^2}{2} \right) - \frac{Wa^2}{2EI} + i_o$$

or

$$i = \frac{Wa}{2lEI} (2lx - x^2 - la) + i_o \quad (3)$$

and

$$\begin{aligned} v &= \frac{Wa}{2lEI} \int (2lx - x^2 - la) dx + i_o \int dx \\ &= \frac{Wa}{2lEI} \left( lx^2 - \frac{x^3}{3} - lax \right) + i_o x + c. \end{aligned}$$

To determine  $c$ , observe that when  $x = a$ , this value of  $v$  and (2) must be identical;

$$\therefore \frac{Wa}{2lEI} \left( -\frac{a^3}{3} \right) + i_o a + c = \frac{W(l-a)}{6lEI} a^3 + i_o a$$

$$\therefore c = \frac{W}{6lEI} (la^3 - a^4 + a^4) = \frac{Wla^3}{6lEI} = \frac{Wa^3}{6EI}$$

$$\therefore v = \frac{Wa}{6lEI} (3lx^2 - x^3 - 3lax + la^2) + i_o x. \quad (4)$$

To determine  $i_o$  we have that when  $x = l$ ,  $v = 0$ ;

$$\therefore 0 = \frac{Wa}{6lEI} (2l^3 - 3al^2 + la^2) + i_o l$$

$$\therefore i_o = \frac{Wa}{6l^2EI} (3al^2 - 2l^3 - la^2) = \frac{Wa}{6lEI} (3al - 2l^2 - a^2).$$

Substituting this value of  $i_o$  in the equations (1), (2), (3), and (4), we obtain for

$$(1) \quad i = \frac{W(l-a)}{2lEI} x^2 + \frac{Wa}{6lEI} (3al - 2l^2 - a^2),$$

$$(2) \quad v = \frac{W(l-a)}{6lEI} x^3 + \frac{Wa}{6lEI} (3al - 2l^2 - a^2)x,$$

$$(3) \quad i = \frac{Wa}{2lEI}(2lx - x^2 - al) + \frac{Wa}{6lEI}(3al - 2l^2 - a^2),$$

$$(4) \quad v = \frac{Wa}{6lEI}(3lx^2 - x^3 - 3lax + la^2) + \frac{Wa}{6lEI}(3al - 2l^2 - a^2)x.$$

To find the greatest deflection, differentiate (2), and place the first differential co-efficient equal to zero: or, which is the same thing, place  $i = 0$  in (1), and find the value of  $x$ ; then substitute this value in (2), and we shall have the greatest deflection.

We thus obtain

$$(l - a)x^2 = \frac{-a}{3}(3al - 2l^2 - a^2) \quad \therefore x^2 = \frac{a}{3} \left( \frac{2l^2 - 3al + a^2}{l - a} \right),$$

or

$$x^2 = \frac{a}{3}(2l - a) \quad \therefore x = \frac{\sqrt{2al - a^2}}{\sqrt{3}};$$

and the greatest deflection becomes

$$v_0 = -\frac{Wa(l - a)(2l - a)}{9lEI} \frac{\sqrt{2al - a^2}}{\sqrt{3}}.$$

## § 200.

### EXAMPLES.

1. In example 1, p. 284, find the greatest deflection of the beam when it is loaded with  $\frac{1}{4}$  of its breaking-load, assuming  $E = 1200000$ .
2. In the same case, find what load will cause it to deflect  $\frac{1}{400}$  of its span.
3. What will be the stress at the most strained fibre when this occurs.
4. In example 3, p. 284, find the load the beam will bear without deflecting more than  $\frac{1}{400}$  of its span, assuming  $E = 24000000$ .
5. Find the stress at the most strained fibre when this occurs.
6. In example 6, p. 285, find the greatest deflection under a load  $\frac{1}{4}$  the breaking-load.

§ 201. **Deflection and Slope under Working-Load.** — If we take the four cases of deflection given in the first part of the table on p. 295, and calling  $f$  the modulus of rupture of the material, and  $y$  the distance of the most strained fibre from the neutral axis, and if we make the applied load the working-load, we shall have respectively —

$$1^{\circ}. \quad Wl = \frac{fI}{y} \quad \therefore \quad W = \frac{fI}{ly}.$$

$$2^{\circ}. \quad \frac{Wl}{2} = \frac{fI}{y} \quad \therefore \quad W = \frac{2fI}{ly}.$$

$$3^{\circ}. \quad \frac{Wl}{4} = \frac{fI}{y} \quad \therefore \quad W = \frac{4fI}{ly}.$$

$$4^{\circ}. \quad \frac{Wl}{8} = \frac{fI}{y} \quad \therefore \quad W = \frac{8fI}{ly}.$$

And the values of slope and deflection will become respectively,

|     | Slope.                      | Deflection.                   |     | Slope.                      | Deflection.                    |
|-----|-----------------------------|-------------------------------|-----|-----------------------------|--------------------------------|
| 1°. | $\frac{1}{2}f \frac{l}{Ey}$ | $\frac{1}{8}f \frac{l^2}{Ey}$ | 3°. | $\frac{1}{2}f \frac{l}{Ey}$ | $\frac{1}{12}f \frac{l^2}{Ey}$ |
| 2°. | $\frac{1}{2}f \frac{l}{Ey}$ | $\frac{1}{8}f \frac{l^2}{Ey}$ | 4°. | $\frac{1}{2}f \frac{l}{Ey}$ | $\frac{1}{48}f \frac{l^2}{Ey}$ |

From these values, and those given on p. 295, we derive the following two propositions: —

1°. If we have a series of beams differing only in length, and we apply the same load in the same manner to each, their greatest slopes will vary as the squares of their lengths, and their greatest deflections as the cubes of their lengths.

2°. If, however, we load the same beams, not with the same load, but each one with its working-load, as determined by allowing a given greatest fibre stress, then will their greatest slopes vary as the lengths, and their greatest deflections as the squares of their lengths.

§ 202. Slope and Deflection of Rectangular Beams. —

If the beams are rectangular, so that  $I = \frac{bh^3}{12}$  and  $y = \frac{h}{2}$ , the values of slope and deflection above referred to become further simplified, and we have the following tables: —

|     | Given Load $W$ .            |                              | Working-Load.<br>Greatest Fibre Stress = $f$ . |                            |
|-----|-----------------------------|------------------------------|--|----------------------------|
|     | Slope.                      | Deflection.                  | Slope.   | Deflection.                |
| 1°. | $\frac{6 W l^2}{E b h^3}$   | $\frac{4 W l^3}{E b h^3}$    | $\frac{f l}{E h}$                              | $\frac{2 f^2 l^2}{3 E h}$  |
| 2°. | $\frac{2 W l^2}{E b h^3}$   | $\frac{3 W l^3}{2 E b h^3}$  | $\frac{2 f l}{3 E h}$                          | $\frac{1 f^2 l^2}{2 E h}$  |
| 3°. | $\frac{3 W l^2}{4 E b h^3}$ | $\frac{1 W l^3}{4 E b h^3}$  | $\frac{1 f l}{2 E h}$                          | $\frac{1 f^2 l^2}{6 E h}$  |
| 4°. | $\frac{1 W l^2}{2 E b h^3}$ | $\frac{5 W l^3}{32 E b h^3}$ | $\frac{2 f l}{3 E h}$                          | $\frac{5 f^2 l^2}{24 E h}$ |

So that, in the case of rectangular beams similarly loaded and supported, we may say that —

Under a given load  $W$ , the slopes vary as the squares of the lengths, and inversely as the breadths and the cubes of the depths; while the deflections vary as the cubes of the lengths, and inversely as the breadths and the cubes of the depths.

On the other hand, under their working-loads, the slopes vary directly as the lengths, and inversely as the depths; while the deflections vary as the squares of the lengths, and inversely as the depths.

§ 203. **Beams Fixed at the Ends.** — The only cases which we shall discuss here are the two following; viz., —

- 1°. Uniform section loaded at the middle.
- 2°. Uniform section, load uniformly distributed.

CASE I. — *Uniform Section loaded at the Middle.* — The fixing at the ends may be effected by building the beam for

FIG. 229.

some distance into the wall, as shown in Fig. 229. The same result, as far as the effect on the beam is concerned, might be effected as follows: Having merely supported it, and placed upon it the loads it has to bear, load the ends outside of the supports just enough to make the tangents at the supports horizontal.

These loads on the ends would, if the other load was removed, cause the beam to be convex upwards: and, moreover, the bending-moment due to this load would be of the same amount at all points between the supports; i.e., a uniform bending-moment. Moreover, since the effect of the central load and the loads on the ends is to make the tangents over the supports horizontal, it follows that the upward slope at the support due to the uniform bending-moment above described must be just equal in amount to the downward slope due to the load at the middle, which occurs when the beam is only supported.

Hence the proper method of proceeding is as follows: —

- 1°. Calculate the slope at the support as though the beam were supported, and not fixed, at the ends; and we shall have, if we represent this slope by  $i$ , the equation

$$i_1 = -\frac{Wl^2}{16EI} \quad (1)$$

2°. Determine the uniform bending-moment which would produce this slope.

To do this, we have, if we represent this uniform bending-moment by  $M_1$ , that the slope which it would produce would be

$$-\frac{M_1 l}{2EI}; \quad (2)$$

and, since this is equal to  $i_1$ , we shall have the equation

$$-\frac{M_1 l}{2EI} - \frac{Wl^2}{16EI} = 0 \quad (3)$$

$$\therefore M_1 = -\frac{Wl}{8}. \quad (4)$$

This is the actual bending-moment at either fixed end; and the bending-moment at any special section at a distance  $x$  from the origin will be

$$M + M_1,$$

where  $M$  is the bending-moment we should have at that section if the beam were merely supported, and not fixed. Hence, when it is fixed at the ends, we shall have, for the bending-moment at a distance  $x$  from  $O$ , where  $O$  is at the left-hand support,

$$M = \frac{W}{2}x - \frac{W}{8}l. \quad (5)$$

When  $x = \frac{l}{2}$ , we obtain, as bending-moment at the middle,

$$M_o = \frac{Wl}{8}; \quad (6)$$

and, since  $M_1 = -M_o$ , it follows that the greatest bending-moment is

$$\frac{Wl}{8},$$

this being the magnitude of the bending-moment at the middle and also at the support.

#### POINTS OF INFLECTION.

The value of  $M$  becomes zero when

$$x = \frac{l}{4} \text{ and when } x = \frac{3l}{4};$$

hence it follows that at these points the beam is not bent, and that we thus have two points of inflection half-way between the middle and the supports.

#### SLOPE AND DEFLECTION UNDER A GIVEN LOAD.

We shall have, as before,

$$i = \int \frac{M}{EI} dx = \frac{Wx^2}{4EI} - \frac{Wlx}{8EI} + c;$$

and since, when  $x = 0$ ,  $i = 0$ ,

$$\therefore c = 0$$

$$\therefore i = \frac{dv}{dx} = \frac{W}{8EI}(2x^2 - lx) \quad (7)$$

$$\therefore v = \frac{W}{8EI}\left(\frac{2x^3}{3} - \frac{lx^2}{2}\right), \quad (8)$$

the constant vanishing because  $v = 0$  when  $x = 0$ . The slope becomes greatest when  $x = \frac{l}{4}$ , and the deflection when  $x = \frac{l}{2}$ .

Hence for greatest slope and deflection, we have

$$i_0 = -\frac{Wl^2}{64EI}, \quad (9)$$

$$v_0 = -\frac{Wl^3}{192EI} \quad (10)$$

## SLOPE AND DEFLECTION UNDER THE WORKING-LOAD.

If  $f$  represent the working-strength of the material per square inch, and if  $W$  represent the centre working-load, we shall have

$$\frac{Wl}{8} = \frac{fI}{y}$$

$$\therefore W = \frac{8fI}{ly} \quad (11)$$

$$\therefore i_0 = -\frac{1}{8} \frac{fl^2}{Ey} \quad (12) \quad v_0 = -\frac{1}{24} \frac{fl^3}{Ey} \quad (13)$$

CASE II. — *Uniform Section, Load uniformly Distributed.* — Pursuing a method entirely similar to that adopted in the former case, we have —

1°. Slope at end, on the supposition of supported ends, is

$$i_1 = -\frac{Wl^2}{24EI} \quad (1)$$

2°. Slope at end under uniform bending-moment  $M_1$  is

$$-\frac{M_1 l}{2EI} \quad (2)$$

Hence, since their sum equals zero,

$$M_1 = -\frac{Wl}{12}, \quad (3)$$

which is the bending-moment over either support.

The bending-moment at distance  $x$  from one end is

$$M = \frac{W}{2l}(lx - x^2) - \frac{Wl}{12}. \quad (4)$$

This is greatest when  $x = 0$ , and is then  $-\frac{Wl}{12}$ . Hence greatest bending-moment is, in magnitude,

$$\frac{Wl}{12}. \quad (5)$$

## POINTS OF INFLECTION.

$$M \text{ becomes zero when } x = \frac{l}{2} \pm \frac{l}{2\sqrt{3}} \quad (6)$$

Hence the two points of inflection are situated at a distance  $\frac{l}{2\sqrt{3}}$  on either side of the middle.

## SLOPE AND DEFLECTION.

$$i = \int \frac{M}{EI} dx = \frac{W}{12lEI} (3lx^2 - 2x^3 - lx), \quad (7)$$

the constant vanishing because  $i = 0$  when  $x = 0$ .

$$v = \frac{W}{12lEI} \left\{ lx^3 - \frac{x^4}{2} - \frac{lx^2}{2} \right\}, \quad (8)$$

the constant vanishing because  $v = 0$  when  $x = 0$ . Hence for greatest slope and deflection we have,  $i$  is greatest when  $x = \frac{l}{2} \left( 1 \pm \frac{1}{\sqrt{3}} \right)$ , and  $v$  is greatest when  $x = \frac{l}{2}$ ;

$$\therefore i_0 = -\frac{Wl^2}{72\sqrt{3}EI}, \quad (9)$$

$$v_0 = -\frac{Wl^3}{384EI}. \quad (10)$$

## SLOPE AND DEFLECTION UNDER WORKING-LOAD.

For working-load we have

$$\frac{Wl}{12} = \frac{fI}{y} \quad (11)$$

$$\therefore W = \frac{12fI}{ly} \quad (12)$$

$$\therefore i_0 = -\frac{fl^2}{6\sqrt{3}Ey}, \quad (13)$$

$$v_0 = -\frac{fl^3}{32Ey}. \quad (14)$$

## EXAMPLES.

1. Given a 4-inch by 12-inch yellow-pine beam, span 20 feet, fixed at the ends; find its safe centre load, its safe uniformly distributed load, and its deflection under each load. Assume a modulus of rupture 5000 lbs. per square inch, and factor of safety 4. Modulus of elasticity, 1200000.

2. Find the depth necessary that a 4-inch wide yellow-pine beam, 20 feet span, fixed at the ends, may not deflect more than one four-hundredth of the span under a load of 5000 lbs. centre load.

§ 204. **Variation of Bending-Moment with Shearing-Force.** — *If, in any loaded beam whatever,  $M$  represent the bending-moment, and  $F$  the shearing-force at a distance  $x$  from the origin, then will*

$$F = \frac{dM}{dx}. \quad (1)$$

*Proof (a).* — In the case of a cantilever (Fig. 230), assume the origin at the fixed end; then, if  $M$  represent the bending-moment at a distance  $x$  from the origin, and  $M + \Delta M$  that at a distance  $x + \Delta x$  from the origin, we shall have the following equations:—

FIG. 230.

$$M = -\sum_{x=x}^{x=l} W(l-x),$$

$$M + \Delta M = -\sum_{x=x}^{x=l} W(l-x-\Delta x) \text{ nearly.}$$

Hence, by subtraction,

$$\Delta M = \Delta x \sum_{x=x}^{x=l} W \text{ nearly}$$

$$\therefore \frac{\Delta M}{\Delta x} = \sum_{x=x}^{x=l} W;$$

and, if we pass to the limit, and observe that

$$F = \sum_{x=0}^{x=l} W,$$

we shall obtain

$$\frac{dM}{dx} = F. \quad (2)$$

(b) In the case of a beam supported at the ends (Fig. 231), assume the origin at the left-hand end, and let the left-hand supporting-force be  $S$ ; then, if  $a$  represent the distance from the origin to the point of application of  $W$ , we shall have the equations

FIG. 231.

$$M = Sx - \sum_{x=0}^{x=x} W(x-a),$$

$$M + \Delta M = S(x + \Delta x) - \sum_{x=0}^{x=x} W(x-a + \Delta x) \text{ nearly.}$$

Hence, by subtraction,

$$\Delta M = S \cdot \Delta x - \sum_{x=0}^{x=x} W \Delta x \text{ nearly}$$

$$\therefore \frac{\Delta M}{\Delta x} = S - \sum_{x=0}^{x=x} W \text{ nearly;}$$

and, if we pass to the limit, and observe that

$$F = S - \sum_{x=0}^{x=x} W,$$

we shall obtain

$$\frac{dM}{dx} = F, \quad (3)$$

as before.

§ 205. **Longitudinal Shearing of Beams.** — The resistance of a beam to longitudinal shearing sometimes becomes a matter of importance, especially in timber, where the resistance to shearing along the grain is very small. We will therefore proceed to ascertain how to compute the intensity of the longitudinal shear at any point of the beam, under any given load; as this should not be allowed to exceed a certain safe limit, to be determined experimentally. Assume a section  $AC$  (Fig. 232) at a distance  $x$  from the origin, and let the bending-moment at that section be  $M$ . Let the section  $BD$  be at a distance  $x + \Delta x$  from the origin, and let the bending-moment at that section be  $M + \Delta M$ .

FIG. 232.

Let  $y_0$  be the distance of the outside fibre from the neutral axis; and let  $ca = y$ , be the distance of  $a$ , the point at which the shearing-force is required, from the neutral axis.

Consider the forces acting on the portion  $ABba$ , and we shall have —

$$1^\circ. \text{ Intensity of direct stress at } A = \frac{My_0}{I}.$$

$$2^\circ. \text{ Intensity of direct stress at a unit's distance from neutral axis} = \frac{M}{I}.$$

$$3^\circ. \text{ Intensity of direct stress at } e, \text{ where } ce = y, \text{ is } \frac{My}{I}.$$

$$\text{So, likewise, intensity of direct stress at } f \text{ is } \frac{(M + \Delta M)y}{I}.$$

Therefore, if  $z$  represent the width of the beam at the point  $e$ , we shall have —

$$\text{Total stress on face } Aa = \frac{M}{I} \int_{y_1}^{y_0} yz dy,$$

$$\text{Total stress on face } Bb = \frac{M + \Delta M}{I} \int_{y_1}^{y_0} yz dy;$$

$$\therefore \text{Difference} = \frac{\Delta M}{I} \int_1^{\infty} yz dy;$$

and this is the total horizontal force tending to slide the piece  $AabB$  on the face  $ab$ .

Area of face  $ab$ , if  $z$ , is its width, is

$$z_1 \Delta x;$$

therefore intensity of shear at  $a$  is approximately

$$\frac{\frac{\Delta M}{I} \int_1^{\infty} yz dy}{z_1 \Delta x},$$

or exactly (by passing to the limit)

$$\frac{\left(\frac{dM}{dx}\right)}{z_1 I} \int_1^{\infty} yz dy.$$

And, observing that  $F = \frac{dM}{dx}$ , this intensity reduces to

$$\frac{F}{z_1 I} \int_1^{\infty} yz dy. \quad (1)$$

We may reduce this expression to another form by observing, that, if  $y_2$  represent the distance from  $c$  to the centre of gravity of area  $Aa$ , and  $A$  represent its area, we have

$$\int_1^{\infty} yz dy = y_2 A;$$

therefore intensity of shear (at distance  $y_1$  from neutral axis) at point  $a =$

$$\frac{F}{z_1 I} (y_2 A). \quad (2)$$

This may be expressed as follows:—

*Divide the shearing-force at the section of the beam under consideration, by the product of the moment of inertia of the section and its width at the point where the intensity of the shearing-force is desired, and multiply the quotient by the statical moment of the portion of the cross-section between the point in question and the outer fibre; this moment being taken about the neutral axis. The result is the required intensity of shear.*

The last factor is evidently greatest at the neutral axis; hence the intensity of the shearing-force is greatest at the neutral axis.

#### LONGITUDINAL SHEARING OF RECTANGULAR BEAMS.

For rectangular beams, we have

$$I = \frac{bh^3}{12}, \quad z_1 = b.$$

Hence formula (2) becomes

$$\frac{12F}{b^2h^3}(y_1A). \quad (3)$$

For the intensity at the neutral axis, we shall have, therefore,

$$\frac{12F}{b^2h^3}\left(\frac{h}{4} \frac{bh}{2}\right) = \frac{3}{2} \frac{F}{bh}, \quad (4)$$

since for the neutral axis we have

$$y_1 = \frac{h}{4} \quad \text{and} \quad A = \frac{bh}{2}.$$

#### EXAMPLES.

1. What is the intensity of the tendency to shear at the neutral axis of a rectangular 4-inch by 12-inch beam, of 14 feet span, loaded at the middle with 5000 lbs.

If we call  $p_2$  the greatest intensity of the tension due to this bending-moment, viz., that at  $B$ , we have

$$p_2 = \frac{P(n+y)y}{I};$$

therefore the actual greatest intensity of the tension is

$$p = p_1 + p_2 = \frac{P}{A} + \frac{P(n+y)y}{I}, \quad (1)$$

and this must be kept within the working-strength if the load is to be a safe one.

EXAMPLES.

1. Suppose the hook to be made of 1-inch diameter iron, and  $n = 1$  inch: what is the working-load, modulus of rupture = 50000 lbs. per square inch, factor of safety 6.

2. A tension-rod hanging vertically bears a load at a horizontal distance of three inches from its centre of gravity: find the necessary diameter, supposing it to be of wrought-iron.

§ 207. **Short Struts.**—The case of a short strut, with the load applied at some point other than the centre of gravity of the section, is similar to that of the hook. Thus, let  $O'$  (Fig. 234) be the centre of gravity of the lower section, and let  $A'O' = x_0$ .

Conceive two equal and opposite forces at  $O'$ , each equal and parallel to  $P$ , and we have—

1°. Downward force along line  $OO'$  causes uniform stress of intensity,

$$p_1 = \frac{P}{A}.$$

2°. The other two form a couple, whose moment is

$$Px_0;$$

FIG. 234.

therefore the greatest intensity of the compression due to this will be that at  $B$ , or

$$p_2 = \frac{(Px_0)a}{I},$$

where  $a = OB$ . Hence total greatest intensity is

$$p = \frac{P}{A} + \frac{Px_0a}{I};$$

or, if we write

$$I = A\rho^2,$$

where  $\rho$  = radius of gyration of lower section about the axis through  $O$  perpendicular to the plane of the paper, we have

$$p = \frac{P}{A} \left( 1 + \frac{x_0a}{\rho^2} \right);$$

and this should be kept within the limits of the working-strength of the material.

#### EXAMPLES.

1. Given a cylindrical column of 8 inches diameter, and let  $x_0 = 2$  inches: find greatest stress per square inch under a load of 100000 lbs.

2. Given  $P = 200000$  lbs.,  $x_0 = 2$  inches: find diameter of a yellow-pine strut suitable to bear the load, with factor of safety 4. Compressive strength of yellow pine = 4400 lbs. per square inch.

§ 208. **Strength of Columns.**—The formulæ in common use for the strength of columns are of three kinds; viz,—

1°. Euler's formulæ, where it is assumed, that, for any given material, there is a certain definite ratio of length to diameter, below which a column will give way by direct crushing, while one whose ratio of length to diameter is greater will give way wholly by transverse bending.

2°. Hodgkinson's empirical formulæ, based upon his experiments upon small columns of a variety of ratios of length to diameter.

3°. Gordon's formulæ, where it is assumed that all columns give way by a combination of crushing and bending.

It is very much to be regretted that none of these sets of formulæ are borne out by experiment upon the large scale, and that thus far we have no formulæ for columns that are borne out generally. Euler's are evidently faulty in the fundamental assumption; Hodgkinson's experiments were made on small columns, and do not agree well with those on large ones; Gordon's, or, as they are otherwise called, Rankine's, are probably correct in their fundamental assumption, but there is a serious lapse in the reasoning by which they are deduced.

The formulæ most frequently used in American practice are those of Gordon. Hence we will take those first.

§ 209. **Gordon's Formulæ for Columns.** (a) *Column fixed in Direction at Both Ends.*—Let  $CAD$  be the central axis of the column,  $P$  the breaking-load, and  $v$  the greatest deflection,  $AB$ . Conceive at  $A$  two equal and opposite forces, each equal to  $P$ ; then—

1°. The downward force at  $A$  causes a uniformly distributed stress over the section, of intensity,

$$p_1 = \frac{P}{A}.$$

2°. The downward force at  $C$  and the upward force at  $A$  constitute a couple, whose moment is

$$M = Pv;$$

and this is resisted, just as the bending-moment in a beam, by a uniformly varying stress, producing compression on the right, and tension on the left, of  $A$ .

If we call  $p_2$  the greatest intensity of the compression due to this bending, we have

$$p_2 = \frac{(Pv)y}{I},$$

where  $y$  = distance from the neutral axis to the most strained fibre of the section at  $A$ . Then will the greatest intensity of the stress of compression at section  $A$  be

$$p = p_1 + p_2 = \frac{P}{A} + \frac{Pvy}{I};$$

and, since  $P$  is the breaking-load,  $p$  must be equal to the breaking-strength for compression per square inch =  $f$ .

Hence

$$f = \frac{P}{A} \left( 1 + \frac{vy}{\rho^2} \right), \quad (1)$$

where  $\rho$  = smallest radius of gyration of section at  $A$ .

Thus far the reasoning appears sound; but in the next step it is assumed, that because, in a loaded beam, the greatest deflection under the breaking-load varies as the square of the length, and inversely as the distance from the neutral axis to the most strained fibre, therefore in this case it is assumed that we must have also

$$v \propto \frac{l^2}{y},$$

or

$$v = \frac{1}{c} \frac{l^2}{y},$$

where  $c$  is a constant to be determined by experiment. Hence

$$vy = \frac{1}{c} l^2;$$

therefore, substituting this in (1),

$$\begin{aligned} \therefore f &= \frac{P}{A} \left\{ 1 + \frac{l^2}{c\rho^2} \right\} \\ \therefore P &= \frac{fA}{1 + \frac{l^2}{c\rho^2}}, \end{aligned} \quad (2)$$

which is the required formula for a column fixed in direction at both ends.

(b) *Column hinged at the Ends.* — It is assumed in the previous case that the points of inflection are halfway between the middle and the ends, and hence that, by taking the middle half, we have the case of bending of a column hinged at the ends (Fig. 236). Hence, to obtain the formula suitable for this case, substitute, in (2),  $2l$  for  $l$ , and we obtain

FIG. 236.

$$P = \frac{fA}{1 + \frac{4l^2}{c\rho^2}} \quad (3)$$

(c) *Column fixed at One End and hinged at the Other* (Fig. 237). — In this case we should, in accordance with these assumptions, take  $\frac{3}{4}$  of the column fixed in direction at both ends; hence, to obtain the formula for this case, substitute, in (2),  $\frac{3}{4}l$  for  $l$ , and we thus obtain

FIG. 237.

$$P = \frac{fA}{1 + \frac{16l^2}{9c\rho^2}} \quad (4)$$

Rankine gives, for values of  $f$  and  $c$ , the following, based upon Hodgkinson's experiments :—

|                        | $f$<br>(lbs. per sq. in.). | $c$ . |
|------------------------|----------------------------|-------|
| Wrought-iron . . . . . | 36000                      | 36000 |
| Cast-iron . . . . .    | 80000                      | 6400  |

§ 210. **Euler's Rules for the Strength of Columns.** — The following are the rules for determining the strength of a column of uniform cross-section, according to Euler:—

(a) *Column fixed in Direction at One End only, which bends, as shown in the Figure.*

1°. Calculate the breaking-load on the assumption that the column will give way by direct compression. This will be

$$P_1 = fA, \quad (1)$$

where  $f$  = crushing-strength per square inch, and  $A$  = area of cross-section in square inches.

2°. Calculate the load that would break the column if it were to give way by bending, by means of the following formula:—

$$P_2 = \left(\frac{\pi}{2l}\right)^2 EI, \quad (2)$$

where  $E$  = modulus of elasticity of the material,  $I$  = smallest moment of inertia of the cross-section, and  $l$  = length of column.

Then will the actual breaking-strength, according to Euler, be the smaller of these two results.

To deduce the latter formula, assume the origin at the hinged end, and take  $x$  vertical and  $y$  horizontal.

FIG. 238.

Let  $\rho$  = radius of curvature at point  $(x, y)$ , and let  $M$  = bending-moment at the same point.

Then we shall have, just as was shown in the case of the deflection of beams,

$$\frac{1}{\rho} = \frac{M}{EI} = \frac{Py}{EI}. \quad (3)$$

But as was there shown,

$$\frac{1}{\rho} = -\frac{d^2y}{dx^2},$$

$$\therefore -\frac{d^2y}{dx^2} = \frac{P}{EI}y,$$

$$\therefore -\int \frac{dy}{dx} \cdot \frac{d^2y}{dx^2} dx = \frac{P}{EI} \int y \frac{dy}{dx} dx$$

$$\therefore \left(\frac{dy}{dx}\right)^2 = -\frac{P}{EI}y^2 + c;$$

and, since for

$$y = a, \quad \frac{dy}{dx} = 0, \quad \therefore c = \frac{P}{EI}a^2$$

$$\therefore \left(\frac{dy}{dx}\right)^2 = \frac{P}{EI}(a^2 - y^2) \quad (4)$$

$$\therefore \frac{dy}{dx} = \sqrt{\frac{P}{EI}}\sqrt{a^2 - y^2}$$

$$\therefore \frac{dy}{\sqrt{a^2 - y^2}} = \sqrt{\frac{P}{EI}} dx$$

$$\therefore \sin^{-1} \frac{y}{a} = \sqrt{\frac{P}{EI}} x + c.$$

And since, when

$$x = 0, \quad y = 0, \quad \therefore c = 0,$$

and we have

$$\sin^{-1} \left(\frac{y}{a}\right) = \sqrt{\frac{P}{EI}} x. \quad (5)$$

When  $y = a$ , we know that  $x = l$ ; hence, substituting in (5), we have

$$\frac{\pi}{2} = \sqrt{\frac{P}{EI}} l,$$

or

$$P = \left(\frac{\pi}{2l}\right)^2 EI. \quad (6)$$

(b) *Column hinged at Both Ends* (Fig. 236).

1°. Calculate the crushing-load, as before, from the formula

$$P_1 = fA.$$

2°. Calculate the load that would break it, if it were to give way wholly by transverse bending, from the formula

$$P_2 = \left(\frac{\pi}{l}\right)^2 EI, \quad (7)$$

this being derived from (2) or (6) by substituting  $\frac{l}{2}$  for  $l$ ; the reasoning being the same for this substitution as was adopted with Gordon's formula.

(c) *Column fixed in Direction at Both Ends* (Fig. 235). —

We have for the crushing-load the same formula as before: viz., —

$$P_1 = fA;$$

and for the bending we have

$$P_2 = \left(\frac{2\pi}{l}\right)^2 EI, \quad (8)$$

this being obtained from (2) or (6) by substituting  $\frac{l}{4}$  for  $l$ .

(d) These rules may be summed up as follows: —

1°. Calculate the crushing-load by the formula

$$P_1 = fA.$$

2°. Calculate the load that would break the column by bending, from the following formulæ: —

$$(a) \quad P_2 = \left(\frac{\pi}{2l}\right)^2 EI$$

if fixed in direction at one end only ;

$$(\beta) \quad P_2 = \left(\frac{\pi}{l}\right)^2 EI$$

if hinged or rounded at both ends ;

$$(\gamma) \quad P_2 = \left(\frac{2\pi}{l}\right)^2 EI$$

if fixed in direction at both ends.

Then will the actual breaking-strength be the least of the two results.

(e) In order to ascertain the length where incipient flexure occurs, according to this theory we should place the two results equal to each other, and from the resulting equation determine  $l$ . We should thus obtain, for the three cases respectively, —

$$(\alpha) \quad l = \frac{\pi}{2} \sqrt{\frac{EI}{fA}}, \quad (9)$$

$$(\beta) \quad l = \pi \sqrt{\frac{EI}{fA}}, \quad (10)$$

$$(\gamma) \quad l = 2\pi \sqrt{\frac{EI}{fA}}. \quad (11)$$

Hence all columns whose length is less than that given in these formulæ will, according to Euler, give way by direct crushing ; and those of greater length, by bending only.

§ 211. **Hodgkinson's Rules for the Strength of Columns.** — Eaton Hodgkinson made a very extensive series of tests of columns, especially of cast-iron, and deduced from these tests certain empirical formulæ. These tests form, even at the present time, the basis of the most used formulæ for the strength of columns. The strength of pillars of the ordinary sizes used in practice has been computed by means of Hodgkinson's for-

mulæ, and tabulated by Mr. James B. Francis: and we find in his book the following rules for the strength of solid cylindrical pillars of cast-iron, with the ends flat; i.e., "finished in planes perpendicular to the axis, the weight being uniformly distributed on these planes."

For pillars whose length exceeds thirty times their diameter, he gives the formula,

$$W = 99318 \frac{D^{3.55}}{l^{1.7}}, \quad (1)$$

where  $D$  = diameter of column in inches,  $l$  = length in feet,  $W$  = breaking-weight in pounds.

If, on the other hand, the length does not exceed thirty times the diameter, he gives, for the breaking-weight, the following formula:—

$$W' = \frac{Wc}{W + \frac{3}{4}c}, \quad (2)$$

where  $W$  = breaking-weight that would be derived from the preceding formula,  $W'$  = actual breaking-weight,  $c$  = weight which would crush the pillar, or

$$c = 109801 \left( \frac{\pi D^3}{4} \right). \quad (3)$$

For hollow cast-iron pillars, if  $D$  = external diameter in inches,  $d$  = internal diameter in inches, we should have, in place of (1),

$$W = 99318 \frac{D^{3.55} - d^{3.55}}{l^{1.7}}, \quad (4)$$

and in place of (3),

$$c = 109801 \frac{\pi(D^3 - d^3)}{4}. \quad (5)$$

For very long wrought-iron pillars, Hodgkinson found the strength to be 1.745 times that of a cast-iron pillar of the same dimensions; but, for very short pillars, he found the strength of

the wrought-iron pillar very much less than that of the cast-iron one of the same dimensions. With a length of 30 diameters and flat ends, the wrought-iron exceeded the cast-iron by about ten per cent.

§ 212. **Strength of Shafting.** — The usual criterion for the strength of shafting is, that it shall be sufficiently strong to resist the twisting to which it is exposed in the transmission of power.

Proceeding in this way, let  $EF$  (Fig. 239) be a shaft,  $AB$  the driving, and  $CD$  the following, pulley. Then, if two cross-sections be taken between these two pulleys, the portion of the shaft between these two cross-sections will, during the transmission of power, be in a twisted condition; and if, when the shaft is at rest, a pair of vertical parallel diameters be drawn in these sections, they will, after it is set in motion, no longer be parallel, but will be inclined to each other at an angle depending upon the power applied. Let  $GH$  be a section at a distance  $x$  from  $O$ , and let  $KI$  be another section at a distance  $x + dx$  from  $O$ . Then, if  $d\theta$  represent the angle at which the originally parallel diameters of these sections diverge from each other, and if  $r =$  the radius of the shaft, we shall have, for the length of an arc passed over by a point on the outside,

FIG. 239.

$$r d\theta;$$

and for the length of an arc that would be passed over if the sections were a unit's distance apart, instead of  $dx$  apart,

$$\frac{r d\theta}{dx} = r \frac{d\theta}{dx}.$$

This is called the *strain* of the outer fibres of the shaft, as it is the distortion per unit of length of the shaft.

In all cases where the shaft is homogeneous and symmetrical, if  $i$  is the angle of divergence of two originally parallel diameters whose distance apart is  $x$ , we shall have the strain,

$$\nu = r \frac{di}{dx} = r \frac{i}{x}.$$

This also is the tangent of the angle of twist.

A fibre whose distance from the axis of the shaft is unity, will have, for its strain,

$$\frac{di}{dx} = \frac{i}{x}.$$

A fibre whose distance from the axis of the shaft is  $\rho$ , will have, for its strain,

$$\nu = \rho \frac{di}{dx} = \rho \frac{i}{x}.$$

Fixing, now, our attention upon one cross-section,  $GH$ , we have that the strain of a fibre at a distance  $\rho$  from the axis ( $\rho$  varying, and being the radius of any point whatever) is

$$\rho \left( \frac{i}{x} \right),$$

where  $\frac{i}{x}$  is a constant for all points of this cross-section.

Hence, assuming Hooke's law, "*Ut tensio sic vis*," we shall have, if  $C$  represent the shearing modulus of elasticity, that the stress of a fibre whose distance from the axis is  $\rho$ , is

$$p = C\nu = C\rho \left( \frac{di}{dx} \right) = C\rho \left( \frac{i}{x} \right),$$

which quantity is proportional to  $\rho$ , or varies uniformly from the centre of the shaft.

The intensity at a unit's distance from the axis is

$$C \left( \frac{i}{x} \right);$$

and if we represent this by  $a$ , we shall have for that at a distance  $\rho$  from the axis,

$$p = a\rho.$$

Hence we shall have (Fig. 240), that, on a small area,

$$dA = d\rho(\rho d\theta) = \rho d\rho d\theta,$$

FIG. 240.

the stress will be

$$p dA = a\rho dA = a\rho^2 d\rho d\theta.$$

The moment of this stress about the axis of the shaft is

$$\rho p dA = a\rho^3 dA = a\rho^3 d\rho d\theta,$$

and the entire moment of the stress at a cross-section is

$$a \int \rho^3 dA = a \int \rho^3 d\rho d\theta = aI,$$

where  $I = \int \rho^2 dA$  is the moment of inertia of the section about the axis of the shaft.

This moment of the stress is evidently caused by, and hence must be balanced by, the twisting-moment due to the pull of the belt. Hence, if  $M$  represent the greatest allowable twisting-moment, and  $a$  the greatest allowable intensity of the stress at a unit's distance from the axis, we shall have

$$M = aI = \frac{p}{\rho} I.$$

If  $f$  is the safe working shearing-strength of the material per square inch, we shall have  $f$  as the greatest safe stress per square inch at the outside fibre, and hence

$$M = \frac{f}{r} I$$

will be the greatest allowable twisting-moment.

For a circle, radius  $r$ ,

$$I = \frac{\pi r^4}{2} \quad \therefore M = f \frac{\pi r^3}{2} = f \frac{\pi d^3}{16}.$$

For a hollow circle, outside radius  $r_1$ , inside radius  $r_2$ ,

$$I = \frac{\pi(r_1^4 - r_2^4)}{2} \quad \therefore M = f \frac{\pi}{2r_1}(r_1^4 - r_2^4).$$

Moreover, if the dimensions of a shaft are given, and the actual twisting-moment to which it is subjected, the stress at a fibre at a distance  $\rho$  from the axis will be found by means of the formula

$$\rho = \frac{M\rho}{I}.$$

The more usual data are the horse-power transmitted and the speed, rather than the twisting-moment.

If we let  $P$  = force applied, and  $R$  = its leverage, as, for instance, when  $P$  = difference of tensions of belt, and  $R$  = radius of pulley, we have

$$M = P \cdot R;$$

and if  $HP$  = number of horses-power transmitted, and  $N$  = number of turns per minute, then

$$HP = \frac{P(2\pi RN)}{33000}$$

$$\therefore PR = \frac{33000HP}{2\pi N} = M.$$

#### EXAMPLE.

Given working-strength for shearing of wrought-iron as 10000 lbs. per square inch; find proper diameter of shaft to transmit 20-horse power, making 100 turns per minute.

§ 213. **Angle of Torsion.** — From the formula, § 212,  $\phi = \frac{M\rho}{I}$ , combined with

$$\phi = a\rho = C\rho \frac{i}{x},$$

we have

$$C\rho \frac{i}{x} = \frac{M\rho}{I}$$

$$\therefore i = \frac{Mx}{CI},$$

which gives the circular measure of the angle of divergence of two originally parallel diameters whose distance apart is  $x$ ; the twisting-moment being  $M$ , and the modulus of shearing elasticity of the material,  $C$ .

#### EXAMPLES.

1. Find the angle of twist of the shaft given in example 1, § 212, when the length is 10 feet, and  $C = 8500000$ .

2. What must be the diameter of a shaft to carry 80 horses-power, with a speed of 300 revolutions per minute, and factor of safety 6, breaking shearing-strength of the iron per square inch being 50000 lbs.

§ 214. **Transverse Deflection of Shafts.** — In determining the proper diameter of shaft to be used in any given case, we ought not merely to consider the resistance to twisting, but also the deflection under the transverse load of the belt-pulls, weights of pulleys, etc. This deflection should not be allowed to exceed  $\frac{1}{100}$  of an inch per foot of length. Hence the deflection should be determined in each case.

The formulæ for computing this deflection will not be given here, as the methods to be pursued are just the same as in the case of a beam, and can be obtained from the discussions on that subject.

§ 215. **Combined Twisting and Bending.** — The most common case of a shaft is for it to be subjected to combined twisting and bending. The discussion of this case involves the theory of elasticity, and will not be treated here; but the formulæ commonly given will be stated, without attempt to prove them until a later period. These formulæ are as follows:—

Let  $M_1$  = greatest bending-moment,

$M_2$  = greatest twisting-moment,

$r$  = external radius of shaft,

$I$  = moment of inertia of section about a diameter,

for a solid shaft  $I = \frac{\pi r^4}{4}$ ,

$f$  = working-strength of the material = greatest allowable stress at outside fibre;

then

1°. According to Grashof,

$$f = \frac{\tau}{J} \left\{ \frac{1}{2} M_1 + \frac{1}{2} \sqrt{M_1^2 + M_2^2} \right\}. \quad (1)$$

2°. According to Rankine,

$$f = \frac{\tau}{J} \left\{ M_1 + \sqrt{M_1^2 + M_2^2} \right\}. \quad (2)$$

## CHAPTER VII.

*STRENGTH OF MATERIALS AS DETERMINED BY  
EXPERIMENT.*

§ 216. **General Remarks.**— Whatever computations are made to determine the form and dimensions of pieces that are to resist stress and strain, must, if they are to have any practical value, be based upon experiments made upon the materials themselves.

The most valuable experiments in any given case, whenever the results of such experiments are available, are those made upon pieces of the same quality, size, and form as those to which the results are to be applied, and under conditions entirely similar to those to which the pieces are subjected in actual practice.

It is very seldom that the results of such experiments are available; and hence we must, in general, make use of such tests as have been or can be made, and from them determine the strength of the pieces in actual use by computation, making good use of our judgment.

As time goes on, and experimental science advances, a greater number of the conditions that exist in actual practice are introduced into the experiments; and hence the reliability of the experimental results, and their applicability to practical cases, are increased. Nevertheless, it is necessary to use the utmost caution when applying the results of the experiments to cases where the conditions are different from those under which the experiments were made. An attempt will be made in this

chapter to give an account of the most important results of experiment on the strength of materials, and to explain the modes of using the results that are now employed. As to the way in which the experiments have generally been carried on, we may observe:—

1°. In by far the greater number of cases, the test pieces have been very much smaller than the pieces to be used. Indeed, it is only of late years that the importance of testing full-size pieces has been recognized; and hence most of the experiments upon such pieces are of very recent date.

2°. In the greater part of the experiments that have been made, the phenomena observed have been those that occur during the application of the load for a short time only; very little having been done by way of determining the behavior of the pieces under a long-continued action of the load, or under repeated applications of the load, such as occur in practice.

3°. Very few experiments have been made on the effect of applying two kinds of stress simultaneously, as tension and bending, or twisting and bending, or on applying stresses of opposite kinds, as tension and compression, successively.

4°. The tests thus far made have had for their object more frequently to determine the breaking-strength of the piece. Next to this, the subject most frequently experimented upon has been the limit of elasticity; and less has been done by way of determining the modulus of elasticity, and other matters.

5°. The fact that the breaking-strength alone is not a sufficient criterion by which to determine the suitability of a material for use in construction, has been recognized only by the later experimenters.

6°. In order to understand what is meant by "the limit of elasticity," we must observe, that, if a small load be applied to the piece under test, and then removed, the deformation or distortion caused by the application of the load apparently vanishes, and the piece resumes its original form and dimensions

on the removal of the load ; in other words, no permanent set takes place. When the load, however, is increased beyond a certain point, the piece under test does not return entirely to its original dimensions on the removal of the load, but retains a certain permanent set.

The load upon the application of which permanent set *apparently* begins, is called the *limit of elasticity*, and is found by experiment to be at about one-third the breaking-weight in iron, and from one-third upwards in steel, sometimes reaching nearly three-fourths.

Experiments show, however, that even a very small load will produce a permanent set, and that the apparent return of the piece to its original dimensions upon the removal of the load is only due to the want of delicacy in the measuring-instruments that have been used in the tests. A better definition of the limit of elasticity would therefore be, that load upon the application of which the permanent set begins to be noticeable, with such rough means of measuring as a pair of dividers.

7°. It has often been assumed, that, if the load applied to the piece in practice exceeded the elastic limit, the piece would be permanently injured in its properties for resisting stress, and that the deformation and injury would continue increasing, until eventually fracture would occur. It has been proved experimentally, however, that it is sometimes advantageous to apply once a load to a piece somewhat greater than the elastic limit, and that by this means the elastic limit is increased. This process of using up a part of the elasticity of the piece cannot continue indefinitely, and the data to show how far it can be advantageously carried are but few.

8°. The determination of the modulus of elasticity, which has been defined (§ 167) as the ratio of the stress to the strain, is a very important matter ; as it gives us the means of computing the deformation under any given load, and thus determining the safe load by prescribing the greatest deformation to

be allowed, rather than by prescribing that the safe load shall be a certain fraction of the breaking-load.

9°. Other important matters which guide us in judging of the suitability of a piece for the purpose to which it is to be applied, are, the appearance of its fracture, its density, its homogeneity, its composition, and the care taken in its manufacture, or the circumstances of its growth and seasoning if it is wood, also its brittleness, hardness, malleability, ductility, the amount of warning it gives before giving way, etc.

10°. From such data as we have furnished to us by experiment, we decide, to the best of our ability, as to the suitability of the piece for the use for which it is intended, and also as to the amount it will safely bear, when we know its dimensions, or the proper dimensions to bear safely the required stress.

11°. Tests have been made on tension, compression, shearing, transverse and torsional strength, of the different materials used in construction, especially cast-iron, wrought-iron, steel, and wood, also copper and other metals; but the tests on tensile strength are by far the most numerous in the case of iron.

§ 217. **Cast-Iron.** — Cast-iron is a combination of iron with 2 per cent to 6 per cent of carbon. The large amount of carbon which it contains is its distinguishing feature, and determines its behavior in most respects.

*Pig-Iron* is the result of the first smelting, being obtained directly from the smelting-furnace. The ore and fuel are put into the furnace, together with a flux, which is of a calcareous nature when the ore is argillaceous, or which contains clay when the ore is calcareous. The mass is brought to a high heat, a strong blast of air being introduced. The mass is thus melted; the fluid iron settling to the bottom, while slag, which is the result of the combination of the flux with the impurities of the ore, rises to the top. The iron is drawn off in the liquid state, and run into moulds, the result being pig-iron.

The result of this first melting is very rarely used for any

casting; but the pig-iron is usually re-melted in a cupola furnace before being used, the result of this re-melting being the ordinary cast-iron of commerce.

The pig-iron is divided into classes, according to the purpose for which it is intended, and the amount of carbon it contains.

Those pigs that have a considerable amount of carbon in mechanical mixture, and show a gray color on being fractured, are used by the founder to melt over, and make cast-iron. This is called "foundry iron," and is divided into foundry iron Nos. 1, 2, and 3, from which are subsequently made gray cast-iron Nos. 1, 2, and 3. When there is less carbon, it is sometimes called "foundry No. 4," etc.; but it is only used to make wrought-iron of an inferior quality.

Those pigs which are to be used in making wrought-iron and steel, and which have been fused at a low heat and with little fuel, are called "forge-iron."

Cast-iron is of two kinds, *white cast-iron* and *gray cast-iron*. The first is a chemical compound of iron with 2 per cent to 6 per cent of carbon, almost all of the carbon being chemically combined with the iron. The second, or gray cast-iron, contains part of the carbon in chemical combination, and the remainder in the state of graphite mechanically mixed with the iron.

*Gray Cast-Iron* is divided into three classes, known respectively as Nos. 1, 2, and 3.

*No. 1* contains the largest amount of carbon in mechanical mixture, the effect of which is to render it soft and fusible, though not as strong as Nos. 2 and 3. It is, therefore, very suitable for making castings where precision in form is a desideratum, as its fusibility causes it to fill the mould well. It is not as suitable, however, where strength is required.

*No. 2* is that which is most suitable for use in construction, as it is stronger than *No. 1*, and not so soft.

*No. 3*, on the other hand, contains the smallest amount of carbon in the graphitic form, and is, hence, harder and more

brittle. It is suited, therefore, only for the massive and heavy parts of machinery.

*White Cast-Iron* contains hardly any free carbon. It is of two kinds, granular and crystalline. The crystalline variety is of no use in construction : it is hard and very brittle. The granular variety is also unsuitable for use in construction, but forms the hard skin on the surface of a piece that has been chilled.

As to the adaptability of cast-iron to construction, it presents certain advantages and certain disadvantages. It is the cheapest form of iron. It is easy to give it any desired form. It resists oxidation better than either wrought-iron or steel. It has a very high compressive strength. On the other hand, its tensile strength is comparatively small, averaging, in common varieties, 15000 pounds per square inch, or thereabouts. It cannot be riveted or welded when broken. It is brittle, breaking off without giving much warning, and stretching but little before giving way. It is liable to hidden and small surface defects and air-bubbles, which render its strength somewhat doubtful. It is also liable to absorb impurities from the fuel or flux in the furnace, the most injurious being sulphur and phosphorus ; the effect of the former being to produce red shortness, or brittleness when hot, and that of the latter to produce cold shortness, or brittleness when cold.

Another very serious drawback in the use of cast-iron in construction is its liability to initial strains from the inequality in cooling. Thus, if one part of the casting is very thin and another very thick, the thin part cools first, and, in cooling, contracts ; and the thick part, cooling afterwards, causes stresses in the thin part, which may be sufficient to break it, or, if not, there may be so much stress established, that but little more will break it. Thus, the change of temperature from summer to winter is sometimes sufficient to break the arms of a pulley from off the rim. Its quality depends largely upon its composition and its density.

The fracture should be of a bluish-gray color, and close-grained texture, with considerable metallic lustre if the iron is of good quality. If the fracture is mottled, with patches of darker or lighter iron, or crystalline spots, it is an indication of unsoundness, especially so if there are air-bubbles.

It is not well adapted to bear tension, on account of its low tensile strength, and also on account of its brittleness and treacherousness.

In former times it was extensively used for iron beams to bear a transverse load, but has now been almost entirely superseded by wrought-iron in this regard.

It is still used for columns and posts in buildings, on account of its high compressive strength; but, in cases where the length of the column is so great as to cause it to give way by bending, as in bridge columns, its use has been almost wholly abandoned, and wrought-iron and steel are taking its place. In the case of bridge columns, it is also necessary to use a metal which can easily be riveted, and to which the other members can be readily attached; and wrought iron is more suitable than cast for this purpose: also another reason is, that wrought-iron and steel are much better suited to resist shocks than cast-iron.

In machinery, it is used in all those parts where weight, mass, or form is of more importance than strength, as in the frames and bed-plates of machines, also for hangers, pulleys, and gear-wheels.

Cast-iron is also used for water-mains where great pressure is to be resisted, also in hydraulic presses, and in heavy ordnance. For shafting, wrought-iron has taken its place, and so also for the shells of steam-boilers, with the exception of some sectional boilers, partly on account of its low tensile strength and general untrustworthiness, but especially because of its liability to give way without warning when subjected to the sudden expansions and contractions which it would have to undergo if used in a steam-boiler.

*Malleable Cast-Iron.*—When a casting is to be made in a rather intricate form, it is frequently the custom to malleableize the cast-iron. This is done by heating it to a bright-red heat in an annealing oven, in powdered hematite ore, with a suitable flux. By this process a part of the carbon is removed, and the result is—provided the casting is not large—a product that can be hammered into any desired shape when cold, but is very brittle when hot. It is used in cases where toughness is required, together with the possession of an intricate form: thus gun-locks, pokers, tongs, etc., are sometimes made by this means, and sometimes also screw propellers.

§ 218. **Tensile and Compressive Strength of Cast-Iron.**

—A list of the principal experimenters on the strength and elasticity of cast-iron will be given, and references to the accounts of their work, which the student who wishes to pursue the subject further will do well to consult:—

- 1°. Eaton Hodgkinson: (a) Report of the Commissioners on the Application of Iron to Railway Structures.  
(b) London Philosophical Transactions. 1840.  
(c) Experimental Researches on the Strength and other Properties of Cast-Iron. 1846.
- 2°. W. H. Barlow: Barlow's Strength of Materials.
- 3°. Sir William Fairbairn: On the Application of Cast and Wrought Iron to Building Purposes.
- 4°. Major Wade (U.S.A.): Report of the Ordnance Department on the Experiments on Metals for Cannon. 1856.
- 5°. Capt. T. J. Rodman: Experiments on Metals for Cannon.
- 6°. Col. Rosset: Resistenza dei Principali Metalli da Bocchi di Fuoco.
- 7°. John Anderson: Strength of Materials.

Taking up first the experiments of Hodgkinson and the other members of the commission, we find that they consist of a series of tests made to compare the strength of iron from different parts of the kingdom. These tests show the average strength of English cast-iron at that time.

The following table gives the tensile and also the crushing strength per square inch of the different kinds tested : —

| Description of the Iron.             | Tensile Strength<br>per<br>Square Inch,<br>in lbs. | Height of<br>Specimen, in<br>inches.                                       | Crushing-Strength<br>per Square Inch,<br>in lbs. |
|--------------------------------------|--|--|--|

The specimens used for determining the tensile strength were all cruciform in section; those for determining the crushing-strength were cylinders, with a diameter of  $\frac{1}{4}$  inch. The machine used was simply a single lever, with a scale-pan at the extreme end, in which weights were placed. There was no provision for taking up the stretch of the specimen, and therefore the specimens were all short.

The average tensile strength of these specimens, omitting the Stirling metal, was 15298 lbs. per square inch; and the average compressive strength was 82296 lbs. per square inch.

It will be observed, that, omitting the Stirling iron, which is a mixture of cast and wrought iron, the tensile strength ranged from 12694 to 23468 lbs. per square inch, and the compressive strength, from 56445 to 117605 lbs. per square inch. The reader will doubtless observe, that, as a rule, the crushing-strengths obtained from the longer specimens were less than those obtained with the shorter ones; but this, it seems to the writer, is probably due to the nature of the testing-machine, and not to any bending in the specimen due to its length.

Mr. Hodgkinson next proceeded to compare the tensile strength of specimens cruciform in section, with that of specimens circular in section and of about the same area. He found but little difference; and this could readily be accounted for by the fact, that, the perimeter of the cruciform one being greater, the proportion of hard skin would be greater in the cruciform than in the circular, the effect of this being, perhaps, partially counteracted by some little initial stress, on account of unequal cooling of the different parts.

Hodgkinson also made a few experiments to determine the laws of extension of cast-iron, and for this purpose used rods 10 feet long and 1 square inch in section. The table of average results is the following:—

## RESULTS OF NINE TENSILE TESTS.

| Weights laid on, in lbs. | Extensions, in inches. | Sets, in inches. | Strains, in fractions of the length. | Sets, in fractions of the length. | Ratio of Weight to Extensions | Modulus of Elasticity. |
|--------------------------|------------------------|------------------|--------------------------------------|-----------------------------------|-------------------------------|------------------------|

These tables show that the modulus of elasticity of cast-iron varies with the load, growing gradually smaller as the load increases.

The following table enables us to compare the modulus of elasticity for tension with that for compression under nearly the same load.

| Tension.                    |                           | Compression.                |                           |
|-----------------------------|---------------------------|-----------------------------|---------------------------|
| Load<br>per Square<br>Inch. | Modulus of<br>Elasticity. | Load<br>per Square<br>Inch. | Modulus of<br>Elasticity. |
| 2107                        | 13597080                  | 2064                        | 13214400                  |
| 4215                        | 12936360                  | 4129                        | 12778200                  |
| 6322                        | 12377040                  | 6194                        | 12434000                  |
| 8430                        | 11776680                  | 8258                        | 12578760                  |
| 10537                       | 11131440                  | 10323                       | 12458280                  |
| 12645                       | 10479480                  | 12388                       | 12357600                  |
| 14793                       | 9549120                   | 14453                       | 12245880                  |

This table shows, that, with moderate loads, the modulus of elasticity for tension of cast-iron does not differ materially from that for compression, and that the difference increases as the load becomes greater.

This fact is one of very considerable importance, inasmuch as it is one of the fundamental assumptions in the common theory of beams; and we thus see that experiment justifies our making this assumption for cast-iron whenever the load is not excessive. The justification is even greater with wrought-iron and steel.

The gradual decrease of the modulus of elasticity with the increase of load shows that Hooke's law, "*Ut tensio sic vis*" (the stress is proportional to the strain), does not hold true in

cast-iron ; nevertheless, it is more nearly true for moderate loads than for larger ones.

The experiments of Major Wade of the United-States army, most of which were made at the South-Boston Iron Foundry, are recorded in the Report of the Ordnance Department on metals for cannon, printed in 1856. The Report contains experiments in regard to the effect of keeping the iron in a state of fusion for a long time, and also on the effect of successive re-meltings upon the quality of the iron ; and he says, —

“ It is found that the same iron is greatly improved in quality by retaining it in the furnace after it is melted for considerable periods of time, and that it is further improved by casting it into pigs, and again re-melting it. But it is known also that a continuation of this process will ultimately impair the tenacity of the iron, and render it wholly unfit for use. It is found also that the different kinds of iron require a different kind of treatment to produce the best effect. The breaking-instrument enables one to ascertain the effect produced by these processes in all their several stages of progress, and to decide on that which is found most suitable for making guns of the best quality.”

On p. 279 of the Report is given the following experiment in this regard :—

“ The first sample was a rough, crude pig of grade No. 1, Greenwood iron.

“ The second, third, and fourth are the same iron, cast and cooled in like manner, and differ only in the number of times melted ; and they exhibit the changes effected in the strength by the repeated meltings only. The fifth sample is from the same melting as the fourth, from which it differs only in cooling, being cast in a large mass, and cooled slowly.”

|        | Fusion. | Tensile Strength. |
|--------|---------|-------------------|
| Pig .  | 1st     | 14000             |
| Bars . | 2d      | 20900             |
|        | 3d      | 30229             |
|        | 4th     | 35786             |
| Head,  | 4th     | 33724             |

The compressive strength of cast-iron tested by Major Wade varied from 84500 lbs. per square inch to 175000 lbs. per square inch. The following table of results of a number of tests of metal taken from different cannon, gives the average tensile strength, specific gravity, and proportion of carbon in the lot of specimens examined :—

|                 | Specific Gravity. | Tensile Strength, lbs., per Square Inch. | Total Carbon. | Combined Carbon. | Allotropic Carbon. |
|-----------------|-------------------|--|---------------|------------------|--------------------|
| 1st-class guns, | 7.204             | 28805                                    | 0.0384        | 0.0178           | 0.0206             |
| 2d-class guns,  | 7.154             | 24767                                    | 0.0376        | 0.0146           | 0.0230             |
| 3d-class guns,  | 7.087             | 20148                                    | 0.0365        | 0.0082           | 0.0283             |

It will be noticed that an increase in tensile strength is generally accompanied by an increase in specific gravity.

Thus another lot of iron gave the following results :—

|           | Tensile Strength, lbs., per Square Inch. | Specific Gravity. |
|-----------|--|-------------------|
| Mean .    | 27232                                    | 7.302             |
| Least .   | 22402                                    | 7.163             |
| Greatest, | 31027                                    | 7.402             |

He also experimented on the difference between hot and cold blast iron, and recommends decidedly the cold blast.

With the hot blast, unless the materials — i.e., the ore, fuel, and flux — are very pure, more of the impurities are fused, and combine with the iron; whereas the iron can be made much more rapidly by its use. Indeed, very little cold-blast charcoal iron is made at the present time; i.e., iron where the blast is cold, and where charcoal is the only fuel used.

The rules of the Ordnance Department of the United States require that all cast-iron which is used for cannon shall have at least a tensile strength of 30000 lbs. per square inch.

The specimens used for testing the tensile strength of cast-iron have generally been made with shoulders: and the smallest part has had, in most cases, no length; and the specimen has had, therefore, very little opportunity to stretch.

Colonel Rosset, of the Arsenal at Turin, made a series of experiments upon the influence of the shape of the specimen upon the tensile strength. For this purpose he used specimens with shoulders; and, among other tests, he compared the strength of the same iron by using specimens the lengths of whose smallest parts were respectively 1 metre, 30 millimetres, and 0 millimetres, with the following results: —

| Length of Specimen. | Tensile Strength, in lbs., per Square Inch. |            |            |
|---------------------|---|------------|------------|
|                     | 1st Cannon.                                 | 2d Cannon. | 3d Cannon. |
| 1 metre . .         | 31291                                       | 25601      | 28019      |
| 30 millimetres .    | 32571                                       | 34562      | 30011      |
| 0 millimetres .     | 33993                                       | 36411      | 30011      |

It will thus be seen, that, before we can decide upon the quality of cast-iron as affected by the tensile strength, it is necessary to know the length of that part of the specimen

which has the smallest area. Colonel Rosset's tests of cast-iron were almost entirely confined to high-grade irons, suitable to use in cannons.

He deduced, for mean value of the modulus of elasticity of the specimens 1 metre in length, 20419658 lbs. per square inch: this, of course, is a modulus only adapted to these high grades, and is not applicable to common cast-iron.

Before proceeding to iron columns, the values given for the tensile and compressive strength, and modulus of elasticity, of cast-iron, in lbs., per square inch, given by Rankine and Weisbach, will be stated; which values are copied by many handbooks:—

|                     |                    | Tensile Strength.      | Compressive Strength.   | Modulus of Elasticity.       |
|---------------------|--------------------|------------------------|-------------------------|------------------------------|
| Professor Rankine . | Various qualities, | { 13400<br>to<br>29000 | { 82000<br>to<br>145000 | { 14000000<br>to<br>22900000 |
|                     | Average . . . .    | 16500                  | 112000                  | 17000000                     |
| Professor Weisbach, | Average . . . .    | 18500                  | —                       | 14220000                     |

### § 219. Cast-Iron Columns. *Hodgkinson's Experiments.*—

The high compressive strength of cast-iron would seem to render it a very suitable material for all cases of columns or struts.

Nevertheless, its use for the compression members of bridge and roof trusses has now been almost entirely abandoned; and wrought-iron has taken its place for these purposes,—partly because these struts are very long, and, if of cast-iron, might, on account of the bending, bring into play its tensile strength; and partly because wrought-iron and steel can be easily riveted, joined to other pieces, and repaired, whereas cast-iron cannot so easily.

Cast-iron is still in use very extensively for the columns of

buildings, as these are generally shorter, and not liable to such varying loads, as is the case with bridges.

Almost the only experiments on the strength of cast-iron columns are those made by Eaton Hodgkinson, and recorded in the London Philosophical Transactions for 1840.

These experiments were made by him at the works of Sir William Fairbairn, who, as he says, put every means for a full investigation into his hands, and expressed the wish that he should extend the inquiry to pillars of various kinds, ancient as well as modern, and leave no part of the subject in uncertainty for the want of experiments sufficiently varied and extensive.

The pillars with which the experiments were made were mostly of cast-iron, as being the material in most general use at that time for that purpose; but some were of wrought-iron, and a few of wood.

Until the time when Hodgkinson made his experiments, the prevailing theory of the strength of columns was that of Euler, which has been already explained in § 210.

According to this theory, a column of any given dimensions and material requires a certain weight to bend it, even in the slightest degree; and, with less than this weight, it would not be bent at all.

This weight producing incipient flexure is to be found, as we have already seen, by the formulæ,

$$P = \left(\frac{\pi}{2l}\right)^2 EI \text{ for one end fixed in direction and the other rounded.}$$

$$P = \left(\frac{\pi}{l}\right)^2 EI \text{ for both ends rounded.}$$

$$P = \left(\frac{2\pi}{l}\right)^2 EI \text{ for both ends fixed in direction, where } l = \text{length of column, } I = \text{moment of inertia of section, } E = \text{modulus of elasticity of the material.}$$

The load  $P$  is, then, according to Euler, the breaking-load unless the column is so short that the breaking-load by direct crushing is less than the value of  $P$ , in which case the column will fail by direct crushing. Starting from this point of view Hodgkinson says, in his report, "My first object was to supply the deficiencies of Euler's theory of the strength of pillars if it should appear capable of being rendered practically useful, and, if not, to endeavor to adapt the experiments so as to lead to useful results." He also says, in regard to Euler's theory, "I have many times sought experimentally, with great care, for the weight producing incipient flexure according to the theory of Euler, but have hitherto been unsuccessful. So far as I can see, flexure commences with weights far below those with which pillars are usually loaded in practice. It seems to be produced by weights much smaller than are sufficient to render it capable of being measured."

"With respect to the conclusions of some writers, that flexure does not take place with less than about half the breaking-weight, this, I conceive, could only mean large and palpable flexure; and it is not improbable that the writers were in some degree deceived, from their having generally used specimens thicker, compared with their length, than have been usually employed in the present effort."

Another matter to which Hodgkinson devoted considerable attention in this investigation, was a comparison of the strength of pillars with flat and with rounded ends respectively. By flat ends is meant having the ends finished in planes perpendicular to the axis, and having the resultant of the weight act along the axis: the ends are then fixed in direction. By rounded ends Hodgkinson actually meant rounded ends; and he used such in his experiments, making them generally hemispherical in form. The results have been assumed generally to apply to pin ends, or to any irregularity of fixing the ends which does not absolutely fix them in direction.

As a result of his experiments, he states, that, in all pillars whose length is thirty times the diameter or upward, the strength of those with flat ends seems to be about three times as great as the strength of those with rounded ends; the mean ratio being 3.167.

In pillars shorter than thirty diameters, the ratio decreased when the ratio of the length to the diameter decreased.

The experiments were all made on circular or hollow circular pillars, the lengths varying from  $7\frac{1}{2}$  diameters to 121 diameters; a case of the first being one  $15\frac{1}{8}$  inches long and 0.51 inch diameter, and of the last,  $30\frac{1}{4}$  inches long and 1.01 inch diameter; the largest diameters used being about two inches.

The empirical formulæ given by Hodgkinson for the strength of cast-iron columns more than thirty diameters long, are as follows; viz., —

#### FOR SOLID CYLINDRICAL COLUMNS.

(a) With rounded ends,

$$P = 33379 \frac{d^{3.6}}{l^{1.7}}; \quad (1)$$

(b) With flat ends,

$$P = 98982 \frac{d^{3.6}}{l^{1.7}}; \quad (2)$$

where  $d$  = diameter in inches,  $l$  = length in feet,  $P$  = breaking-weight in pounds.

#### FOR HOLLOW CYLINDRICAL COLUMNS.

(a) With rounded ends,

$$P = 29120 \frac{D^{3.6} - d^{3.6}}{l^{1.7}}; \quad (3)$$

(b) With flat ends,

$$P = 99318 \frac{D^{3.6} - d^{3.6}}{l^{1.7}}; \quad (4)$$

where  $D$  = outside diameter,  $d$  = inside diameter in inches, and  $l$  = length in feet.

For columns less than thirty diameters long, Hodgkinson gives the following formula for the breaking-strength:—

$$y = \frac{bc}{b + \frac{3}{4}c}, \quad (5)$$

where  $c$  = force which would crush the pillar without bending it,  $b$  = breaking-weight that would be obtained by using the formula for columns more than thirty diameters long,  $y$  = actual breaking-strength.

For determining the value of  $c$ , we have as the crushing-strength of cast-iron, from some experiments of Hodgkinson made at the time on cast-iron, the value 109801 lbs. per square inch; so that we should have,

For solid circular columns,

$$c = 109801 \frac{\pi d^2}{4}; \quad (6)$$

For hollow circular columns,

$$c = 109801 \frac{\pi (D^2 - d^2)}{4}. \quad (7)$$

The number 33379 of equation (1) is the mean result from eighteen pillars, varying in length from 121 times the diameter down to 15 times the diameter; the 98982 of equation (2) is similarly obtained from eleven pillars, varying in length from 78 to 25 times the diameter.

Mr. James B. Francis has computed and published a series

of tables of the strength of cast-iron pillars of the ordinary sizes used in practice, the computations being made by means of Hodgkinson's formulæ.

We have also Gordon's formulæ, which have been already given in § 209, the constants of which are based upon Hodgkinson's experiments. While we have, in the case of wrought-iron and wood, the results of experiments made upon full-size columns, which furnish us more reliable data upon which to base our conclusions in designing such columns, we have, in the case of cast-iron, no way of obtaining more reliable data than those furnished by Hodgkinson's experiments; and hence we can use these results only with a large factor of safety. Mr. Francis recommends five.

§ 220. **Transverse Strength of Cast-Iron.**—At one time cast-iron was very largely used for beams and girders to support a transverse load. Its use for this purpose has now been almost entirely abandoned, as it has been superseded by wrought-iron.

A great many experiments have been made on the transverse strength of cast-iron; the specimens used in some cases being small, and in others large. The records of a great many experiments of this kind are to be found in the first four books of the list already enumerated in § 218. The details of these tests will not be considered here, but an outline will be given of some of the main difficulties that arise in applying the results and in using the beams.

That cast-iron is treacherous and liable to hidden flaws; and that it is brittle, is well known by all who use it. It is also a fact, that in casting any piece where the thickness varies in different parts, the unequal cooling is liable to establish initial strains in the metal, and that, therefore, those parts where such strains have been established have their breaking-strength diminished in proportion to the amount of these strains. These defects are enough to exclude cast-iron from use for beams when we have a much better material in wrought-iron.

Another element of uncertainty, which has vexed experimenters, and which has not yet received a complete solution, is the fact, that whereas we can, with some approximation to correct results, predict the strength of a wrought-iron beam, from simply knowing the tensile and compressive strength of the iron per square inch, by applying our ordinary theory of beams, it is impossible to do so in the case of a cast-iron beam. Thus, in the case of a cast-iron which would have a tensile strength of 16000 to 18000 lbs. per square inch, and a compressive strength of about 80000 lbs. per square inch, the modulus of rupture would be variable, but very seldom either of these two numbers.

In Rankine's tables, the modulus of rupture for rectangular beams of cast-iron is given on the average as 40000 lbs. per square inch, and that for openwork beams as 17000.

What the meaning of this discrepancy was, and how to get a uniform modulus of rupture, engaged the attention of many experimenters. One explanation offered was, that the neutral axis was not at the centre of gravity of the section, but that its position was in some way affected by the relation between the tensile and the compressive strength of the iron. A moment's thought, and a consideration of the assumptions made in the common theory of beams, will show the absurdity of any such conclusion. As well might we conclude that a loaded beam, resting on two supports at the ends, would have its pressure on these supports regulated by the strength of the supports, instead of by the principle of the lever.

Besides this, the younger Barlow tried an experiment to determine the position of the neutral axis in a rectangular cast-iron beam, and found it at the middle of the depth.

The elder Barlow proposed a very elaborate explanation, deducing some much more complicated formulæ for the strength of beams than the ordinary ones; but there is not good evidence of the truth of this theory.

The most plausible explanation seems to be that offered by Rankine; viz., that, besides unequal cooling and the consequent establishing of initial strains, the variation is caused by the proportion of the hardened, tough skin of the metal. This skin theory is borne out, to a great extent, by a series of tests made by Edwin Clark, and detailed in D. K. Clark's "Rules and Tables," p. 562.

§ 221. **Wrought-Iron.** — Wrought-iron is the product obtained by removing the carbon from cast-iron. It is produced by melting the iron, and passing an oxidizing flame over it. When the carbon is burned out, the mass of iron is left in a pasty condition, full of holes. It is then taken out, and hammered or rolled in order to unite it into one mass. Wrought-iron is thus, from the commencement of its manufacture, a series of welds; and the perfection or imperfection of these welds affects very seriously the quality of the iron.

The result of this first process is not suitable to use in any construction of importance; but it requires to be re-heated and re-rolled a number of times, in order to make it more homogeneous, and to remove flaws from within the iron.

At best, however, wrought-iron is a series of welds; and, if a piece be broken, the separate layers of which it is composed can be seen plainly. It is also subject to the impurities of the cast-iron from which it is made. Thus, the presence of sulphur makes it red-short, or brittle when hot; and the presence of phosphorus makes it cold-short, or brittle when cold.

It cannot, like cast-iron, be melted and run into moulds; but it can be welded; that is, two masses of wrought-iron can be united by being brought to a proper temperature, and then hammered together.

Wrought-iron is much more capable of bearing a tensile or transverse stress than cast-iron: it is tougher, it stretches more, and gives more warning before fracture. At one time cast-iron was almost the only form in which iron was used in

construction ; but now wrought-iron and steel are superseding it in by far the majority of cases where strength and toughness, and the ability to resist varied stresses, are demanded.

Wrought-iron is also expected to withstand a great many trials that would seriously injure cast-iron : thus, two pieces of wrought-iron are generally united together by riveting ; the holes for the rivets have to be punched or drilled, and then the rivets have to be hammered ; the entire process tending to injure the iron. Wrought-iron has to withstand flanging, and is liable to severe shocks when in use ; as, for instance, those that occur from the difference of temperature, and the changes of temperature in the different parts of a steam-boiler.

§ 222. **Tensile and Compressive Strength of Wrought-Iron.**—As to the experimenters on the tensile strength and elasticity of wrought-iron, those who preceded Hodgkinson are of little more than historic interest. The following list includes a number of the most known experimenters :—

- 1°. Eaton Hodgkinson : (a) Report of Commissioners on the Application of Iron to Railway Structures.  
(b) London Philosophical Transactions. 1840.
- 2°. William H. Barlow : Barlow's Strength of Materials.
- 3°. Sir William Fairbairn : On the Application of Cast and Wrought Iron to Building Purposes.
- 4°. Franklin Institute Committee : Report of the Committee of the Franklin Institute. In the Franklin Institute Journal of 1837.
- 5°. L. A. Beardslee, Commander, U.S.N. : Experiments on the Strength of Wrought-Iron and of Chain Cables. Revised and enlarged by William Kent, M.E., or Executive Document 98, 45th Congress, as stated below.

- 12°. Professor R. H. Thurston: Materials of Engineering.

A few tests were made on the tensile strength of wrought-iron by Eaton Hodgkinson; two of these were on the tensile strength and elasticity of rods about fifty feet long; each rod being made in three parts, these parts being united by couplings.

Below is given the table of results of the first of these tests, as recorded in the commissioners' report, to which table is added here the column of modulus of elasticity:—

| Weights applied, in lbs. | Extension, in inches. | Sets, in inches.           | Weights per Square Inch of Section, in lbs. | Strains, in Fractions of the Length. | Sets, in Fractions of the Length. | Ratio of Weight to Extension. | Modulus of Elasticity. |

With this last weight the rod broke at one of the weldings, where there was a slight defect; perhaps a rather smaller weight would have broken it.

In connection with this table of results, the following observations will be made:—

1°. The breaking-strength per square inch in this case was 53351 lbs. per square inch.

2°. Permanent set began with very small loads.

3°. The limit of elasticity was about 29000 lbs. per square inch, this being about the load where permanent set began to increase rapidly.

4°. The modulus of elasticity of the rod in this case was about 28000000 lbs. per square inch, this being the ratio of the stress to the strain under loads less than the limit of elasticity.

5°. This experiment shows, that, under moderate loads, the modulus of elasticity, and hence the ratio of the stress to the strain, remains much more nearly constant with wrought than with cast iron.

6°. The other experiment, with a rod 50 feet long, gave as modulus of elasticity 27691200 lbs. per square inch.

The remaining experiments of Hodgkinson on wrought-iron may be found in the report of the commissioners already referred to.

*Barlow's* experiments on wrought-iron will not be detailed here, except only to say that he tried seven experiments to determine the modulus of elasticity of wrought-iron, and that he obtained, for mean extension per English ton per square inch, maximum, 0.0001082; minimum, 0.0000841; mean, 0.0000956 of the length. These correspond to moduli of elasticity respectively equal to 20702400, 26634900, and 23430900 lbs. per square inch.

The results obtained by experimenters before Hodgkinson's time are very discordant and very uncertain, many of them attributing to wrought-iron a strength far greater than

can be attained at the present time. There is no satisfactory evidence, however, to show that the wrought-iron of that time was any better than (if as good as) that made at the present time; and it is more probable either that there were errors in making the tests, or else that the supposed iron was really steel and possibly brittle. The paucity of the records, and the impossibility of obtaining the details of the tests, render any search for the reason in any special cases futile, and throw doubt upon the greater part of these tests.

Among the later English experimenters, we have Sir William Fairbairn. An account of his tests on tensile strength will be found in the book already referred to.

One of the most prominent English experimenters, and one who has done a great deal towards rendering our knowledge of this subject more accurate, is David Kirkaldy. His results up to 1866 are detailed in his book entitled, "Experiments on Wrought-Iron and Steel," published in that year.

In the early part of his book will be found a summary of what had been done in this line by the early experimenters.

Kirkaldy tested a large number of English irons; and a summary of his results will be given here, together with his sixty-six concluding observations.

Fracture 1-12. — Light gray of various shades, close and very fine.

Fracture 13-30. — Dullish gray of various shades, close and generally fine.

Fracture 31-44. — Dull gray, generally rather coarse and irregular.

Fracture 45-52. — Irregular, generally coarse and open.

Fracture 53. — Close and fine.

## KIRKALDY'S SIXTY-SIX CONCLUSIONS.

1°. The breaking-strain does not indicate the quality, as hitherto assumed.

2°. A high breaking-strain may be due to the iron being of superior quality, dense, fine, and moderately soft, or simply to its being very hard and unyielding.

3°. A low breaking-strain may be due to looseness and coarseness in the texture, or to extreme softness, although very close and fine in quality.

4°. The contraction of area at fracture, previously overlooked, forms an essential element in estimating the quality of specimens.

5°. The respective merits of various specimens can be correctly ascertained by comparing the breaking-strain jointly with the contraction of area.

6°. Inferior qualities show a much greater variation in the breaking-strain than superior.

7°. Greater differences exist between small and large bars in coarse than in fine varieties.

8°. The prevailing opinion of a rough bar being stronger than a turned one, is erroneous.

9°. Rolled bars are slightly hardened by being forged down.

10°. The breaking-strain, and contraction of area, of iron plates are greater in the direction in which they are rolled than in a transverse direction.

11°. A very slight difference exists between specimens from the centre and specimens from the outside of crank-shafts.

12°. The breaking-strain, and contraction of area, are greater in those specimens cut lengthways out of crank-shafts than in those cut cross-ways.

13°. The breaking-strain of steel, when taken alone, gives no clew to the real qualities of various kinds of that material.

14°. The contraction of area at fracture of specimens of steel must be ascertained, as well as in those of iron.

15°. The breaking-strain, jointly with the contraction of area, affords the means of comparing the peculiarities in various lots of specimens.

16°. Some descriptions of steel are found to be very hard, and consequently suitable for some purposes; whilst others are extremely soft, and equally suitable for other uses.

17°. The breaking-strain, and contraction of area, of puddled steel plates, as in iron plates, are greater in the direction in which they are rolled; whereas in cast-steel they are less.

18°. Iron, when fractured suddenly, presents invariably a crystalline appearance; when fractured slowly, its appearance is invariably fibrous.

19°. The appearance may be changed from fibrous to crystalline by merely altering the shape of the specimen so as to render it more liable to snap.

20°. The appearance may be changed by varying the treatment so as to render the iron harder and more liable to snap.

21°. The appearance may be changed by applying the strain so suddenly as to render the specimen more liable to snap from having less time to stretch.

22°. Iron is less liable to snap the more it is worked and rolled.

23°. The "skin," or outer part of the iron, is somewhat harder than the inner part, as shown by appearance of fracture in rough and turned bars.

24°. The mixed character of the scrap-iron used in large forgings is proved by the singularly varied appearance of the fractures of specimens cut out of crank-shafts.

25°. The texture of various kinds of wrought-iron is beautifully developed by immersion in dilute hydrochloric acid, which, acting on the surrounding impurities, exposes the metallic portion alone for examination.

26°. In the fibrous fractures the threads are drawn out, and are viewed externally; whilst in the crystalline fractures the threads are snapped across in clusters, and are viewed internally or sectionally. In the latter cases, the fracture of the specimen is always at right angles to the length; in the former, it is more or less irregular.

27°. Steel invariably presents, when fractured slowly, a silky, fibrous appearance; when fractured suddenly, the appearance is invariably granular, in which case also the fracture is always at right angles to the length; when the fracture is fibrous, the angle diverges always more or less from 90°.

28°. The granular appearance presented by steel suddenly fractured is nearly free from lustre, and unlike the brilliant crystalline appearance of iron suddenly fractured: the two combined in the same specimen are shown in iron bolts partly converted into steel.

29°. Steel which previously broke with a silky, fibrous appearance is changed into granular by being hardened.

30°. The little additional time required in testing those specimens

whose rate of elongation was noted, had no injurious effect in lessening the amount of breaking-strain, as imagined by some.

31°. The rate of elongation varies not only extremely in different qualities, but also to a considerable extent in specimens of the same brand.

32°. The specimens were generally found to stretch equally throughout their length until close upon rupture, when they more or less suddenly draw out; usually at one part only, sometimes at two, and in a few exceptional cases at three, different places.

33°. The ratio of ultimate elongation may be greater in short than in long bars in some descriptions of iron; whilst in others the ratio is not affected by difference in the length.

34°. The lateral dimensions of specimens form an important element in comparing either the rate of or the ultimate elongations,—a circumstance which has been hitherto overlooked.

35°. Steel is reduced in strength by being hardened in water, while the strength is vastly increased by being hardened in oil.

36°. The higher steel is heated (without, of course, running the risk of being burned), the greater is the increase of strength by being plunged into oil.

37°. In a highly converted or hard steel the increase in strength and in hardness is greater than in a less converted or soft steel.

38°. Heated steel, by being plunged into oil instead of water, is not only considerably *hardened*, but *toughened*, by the treatment.

39°. Steel plates hardened in oil and joined together with rivets are fully equal in strength to an unjointed soft plate, or, the loss of strength by riveting is more than counterbalanced by the increase in strength by hardening in oil.

40°. Steel rivets fully larger in diameter than those used in riveting iron plates of the same thickness, being found to be greatly too small for riveting steel plates, the probability is suggested that the proper proportion for iron rivets is not, as generally assumed, a diameter equal to the thickness of the two plates to be joined.

41°. The shearing-strain of steel rivets is found to be about a fourth less than the tensile strain.

42°. Iron bolts case-hardened bore a less breaking-strain than when

wholly iron, owing to the superior tenacity of the small proportion of steel being more than counterbalanced by the greater ductility of the remaining portion of iron.

43°. Iron highly heated, and suddenly cooled in water, is hardened, and the breaking-strain, when gradually applied, increased; but at the same time it is rendered more liable to snap.

44°. Iron, like steel, is softened, and the breaking-strain reduced, by being heated, and allowed to cool slowly.

45°. Iron subjected to the cold-rolling process has its breaking-strain greatly increased by being made extremely hard, and not by being "consolidated," as previously supposed.

46°. Specimens cut out of crank-shaft are improved by additional hammering.

47°. The galvanizing or tinning of iron plates produces no sensible effects on plates of the thickness experimented on. The results, however, may be different should the plates be extremely thin.

48°. The breaking-strain is materially affected by the shape of the specimen. Thus, the amount borne was much less when the diameter was uniform for some inches of the length than when confined to a small portion,—a peculiarity previously unascertained and not even suspected.

49°. It is necessary to know correctly the exact conditions under which any tests are made, before we can equitably compare results obtained from different quarters.

50°. The startling discrepancy between experiments made at the Royal Arsenal and by the writer is due to the difference in the shape of the respective specimens, and not to the difference in the two testing-machines.

51°. In screwed bolts, the breaking-strain is found to be greater when old dies are used in their formation than when the dies are new, owing to the iron becoming harder by the greater pressure required in forming the screw-thread when the dies are old and blunt than when new and sharp.

52°. The strength of screw-bolts is found to be in proportion to their relative areas; there being only a slight difference in favor of the smaller compared with the larger sizes, instead of the very material difference previously imagined.

53°. Screwed bolts are not necessarily injured, although strained nearly to their breaking-point.

54°. A great variation exists in the strength of iron bars which have been cut and welded: whilst some bear almost as much as the uncut bar, the strength of others is reduced fully a third.

55°. The welding of steel bars, owing to their being so easily burned by slightly over-heating, is a difficult and uncertain operation.

56°. Iron is injured by being brought to a white or welding heat if not at the same time hammered or rolled.

57°. The breaking-strain is considerably less when the strain is applied suddenly, instead of gradually, though some have imagined that the reverse is the case.

58°. The contraction of area is also less when the strain is suddenly applied.

59°. The breaking-strain is reduced when the iron is frozen. With the strain gradually applied, the difference between a frozen and unfrozen bolt is lessened as the iron is warmed by the drawing-out of the specimen.

60°. The amount of heat developed is considerable when the specimen is suddenly stretched, as shown in the formation of vapor from the melting of the layer of ice on one of the specimens, and also by the surface of others assuming tints of various shades of blue and orange, not only in steel, but also, although in a less marked degree, in iron.

61°. The specific gravity is found generally to indicate pretty correctly the quality of specimens.

62°. The density of iron is *decreased* by the process of wire-drawing, and by the similar process of cold-rolling, instead of *increased*, as previously imagined.

63°. The density in some descriptions of iron is also decreased by additional hot-rolling in the ordinary way: in others the density is very slightly increased.

64°. The density of iron is decreased by being drawn out under a tensile strain, instead of increased, as believed by some.

65°. The most highly converted steel does not, as some may suppose, possess the greatest density.

66°. In cast-steel the density is much greater than in puddled steel, which is even less than in some of the superior descriptions of wrought-iron.

#### TESTS OF COMMANDER BEARDSLEE.

One of the most valuable sets of tests of wrought-iron is that obtained by committees D, H, and M of the Board appointed by the United-States Government to test iron and steel; the special duties of these committees being to test such iron as would be used in chain-cable, and the chain-cable itself. The chairman of these three committees, which were consolidated into one, was Commander L. A. Beardslee of the United-States Navy. The full account of the tests is to be found in Executive Document 98, 45th Congress, second session; and an abridged account of them was published by William Kent, as has been already mentioned.

The samples of bar-iron tested were round, and varied from one inch to four inches in diameter. The mills from which the samples tested came were as follows:—

|   |                |
|---|----------------|
| Bentoni . . . . .                           | Pennsylvania.  |
| Burden and Sons . . . . .                   | New York.      |
| Burgess . . . . .                           | Ohio.          |
| Catasauqua . . . . .                        | Pennsylvania.  |
| New-Jersey Iron and Steel Company . . . . . | New Jersey.    |
| Niles Iron Company . . . . .                | Ohio.          |
| Pembroke . . . . .                          | Massachusetts. |
| Pencoyd . . . . .                           | Pennsylvania.  |
| Phoenix . . . . .                           | Pennsylvania.  |
| Sligo . . . . .                             | Pennsylvania.  |
| Tamaqua . . . . .                           | Pennsylvania.  |
| Tredegear . . . . .                         | Virginia.      |
| Trego and Thompson . . . . .                | Maryland.      |
| Wyeth Brothers . . . . .                    | Maryland.      |

Certain conclusions which they reached refer to all kinds of wrought-iron, and will be given here before giving a table of the results of the tests.

1°. Kirkaldy considers the breaking-strength per square inch of fractured area as the main criterion by which to determine the merits of a piece of iron or steel. Commander Beardslee, on the other hand, thinks that a better criterion is what he calls the "tensile limit;" i.e., the maximum load the piece sustains divided by the area of the smallest section when that load is on, i.e., just before the load ceases to increase in the testing-machine.

2°. Kirkaldy had already called attention to the fact that the tensile strength of a specimen is very much affected by its shape, and that, in a specimen where the shape is such that the length of that part which has the smallest cross-section is practically zero (as is the case when a groove is cut around the specimen), the breaking-strength is greater than it is when this portion is long; the excess being in some cases as much as 33 per cent.

Commander Beardslee undertook, by actually testing specimens whose smallest areas varied in length, to determine what must be the least length of that part of the specimen whose cross-section area is smallest, in order that the tensile strength may not be greater than with a long specimen. The conclusion reached was, that no test-piece should be less than one-half inch in diameter, and that the length should never be less than four diameters; while a length of five or six diameters is necessary with soft and ductile metal in order to insure correct results. The following results of testing steel are given in Mr. Kent's book, as confirming the same rule in the case of steel. The tests were made upon Bessemer steel by Col. Wilmot at the Woolwich arsenal.

|                          | Tensile Strength. | Pounds per Square Inch. |
|--------------------------|-------------------|-------------------------|
| By groove form . . . . . | Highest . . . . . | 162974                  |
|                          | Lowest . . . . .  | 136490                  |
|                          | Average . . . . . | 153677                  |
| By cylinder . . . . .    | Highest . . . . . | 123165                  |
|                          | Lowest . . . . .  | 103255                  |
|                          | Average . . . . . | 114460                  |

3°. Commander Beardslee also noticed that rods of certain diameters of the same kind of iron bore less in proportion than rods of other diameters; and, after searching carefully for the reason, he found it to lie in the proportion between the diameter of the rod and the size of the pile from which it is rolled. The following examples are given:—

|                     |           |        |          |       |                                    |
|---------------------|-----------|--------|----------|-------|------------------------------------|
| $1\frac{1}{8}$ -in. | diameter, | 6.62%  | of pile, | 56543 | lbs. per sq. in. tensile strength. |
| $1\frac{1}{4}$      | "         | 8.18%  | "        | 56478 | " " " "                            |
| $1\frac{3}{8}$      | "         | 9.90%  | "        | 54277 | " " " "                            |
| $1\frac{1}{2}$      | "         | 11.78% | "        | 53550 | " " " "                            |
| $1\frac{5}{8}$      | "         | 7.68%  | "        | 56344 | " " " "                            |
| $1\frac{3}{4}$      | "         | 8.90%  | "        | 55018 | " " " "                            |
| $1\frac{7}{8}$      | "         | 10.22% | "        | 54034 | " " " "                            |
| 2                   | "         | 11.63% | "        | 51848 | " " " "                            |

He therefore claims, that, in any set of tests of round iron, it is necessary to give the diameter of the rod tested, and not merely the breaking-strength per square inch.

4°. He gives evidence to show, that if a bar is under-heated, it will have an unduly high tenacity and elastic limit; and that if it is over-heated, the reverse will be the case.

5°. The discovery was made independently by Commander Beardslee and Professor Thurston, that wrought-iron, after having been subjected to its ultimate tensile strength without breaking it, would, if relieved of its load and allowed to rest, have its breaking-strength and its limit of elasticity increased.

He tried a considerable number of experiments, studying the action of this law under different periods of rest, from 1 minute to 3 days and upwards; and a great deal of valuable information is given in the tables of the report.

The most characteristic table is the following :—

EFFECT OF EIGHTEEN HOURS' REST ON IRONS OF WIDELY DIFFERENT CHARACTERS.

|                      | Ultimate Strength<br>per Square Inch. |                   | Remarks.                    |
|----------------------|---------------------------------------|-------------------|-----------------------------|

His experiments show that the increase is in irons of a fibrous and ductile nature, rather than in brittle and steely ones : hence the latter class would be but little benefited by the action of this law.

The following table of results is given in the report ; showing how the strength per square inch varies with the diameter of the piece, in consequence of the amount of reduction in the rolls.

| Diameter, in inches. | Name of Iron. | Strength per Square Inch of Original Area. | Elastic Limit per Square Inch of Original Area. | Diameter, in inches. | Name of Iron. | Strength per Square Inch of Original Area. | Elastic Limit per Square Inch of Original Area. | Diameter, in inches. | Name of Iron. | Strength per Square Inch of Original Area. | Elastic Limit per Square Inch of Original Area. |

## TENSILE TESTS MADE SUBSEQUENTLY AT THE WATERTOWN ARSENAL.

Here will next be given, in tabulated form, the results of a number of tensile tests made on the government machine at the Watertown Arsenal.

*The following tables of results on rolled bars, from the Elmira Rolling-Mill Company (mark L) and from the Passaic Rolling-Mills (mark S), are given in Executive Document 12, 47th Congress, 1st session, and in Executive Document 1, 47th Congress, 2d session.*

## SINGLE REFINED BARS.

| Mark on Bar. |    | Sectional Area, in square inches. | Elastic Limit, in lbs., per Square Inch. | Ultimate Strength, in lbs., per Square Inch. | Elongation in 80 inches, %. | Contraction of Area, %. | Appearance of Fracture. |                  | Modulus of Elasticity at Load of 20000 Lbs. per Square Inch. |        |
|--------------|----|-----------------------------------|--|--|-----------------------------|-------------------------|-------------------------|------------------|--|--------|
|              |    |                                   |  |  |                             |                         | Fibrous, %.             | Crystal-line, %. |  |        |

The moduli of elasticity had not been computed in the report, but have been computed in these tables from the elongations under a load of 20000 lbs. per square inch in each case, as recorded in the details of the tests.

In these reports are also to be found tensile tests of iron from other companies, as the Detroit Bridge Company, the Phoenix Company, the Pencoyd Company, etc. Some of these

tests were made to determine the effect of rest upon the bar after it had been strained to its ultimate strength. Some were made to determine the values of the modulus of elasticity of the same iron for tension and for compression; and these were found experimentally to be almost identical, as was to be expected. For these tests the student is referred to the reports themselves; and only certain tests on eye-bars of the Phoenix Company will be appended here. Some of them were tested only for modulus of elasticity, which are not calculated in the report, but are given here.

| Arsenal Number. | Outside Length, inches. | Gauged Length, inches. | Sectional Area, square inches. | Modulus of Elasticity. | Ultimate Strength, lbs., per Sq. In. | Contraction of Area at Fracture, %. |

Quite a number of tests of the iron of different American companies are to be found in the "Report on the Progress of Work on the Cincinnati Southern Railway," by Thomas D. Lovett, Nov. 1, 1875.

For these the student is referred to the report named.

## SPECIAL MODULUS OF ELASTICITY.

In connection with Hodgkinson's experiment on a bar 50 feet long, attention was called to the fact that the modulus of elasticity remained more nearly constant in wrought than in cast iron for loads below the limit of elasticity, and that, after passing this limit, the modulus of elasticity decreases rapidly, inasmuch as the strain increases very much more rapidly than the stress.

This could be represented graphically by drawing a curve, having for abscissæ of its several points the loads per square inch applied to the piece, and for ordinates the elongations or shortenings. Such a curve would, in the case of wrought-iron, be nearly a straight line up to the limit of elasticity, and then would rise very rapidly.

If, now, we should plot another curve with the same abscissæ as before, but having for ordinates the permanent sets under the respective loads, this curve would start from the axis of abscissæ at the limit of elasticity, and rise rapidly from that point on.

Again : if another curve be drawn, having the same abscissæ as before, but having for ordinates in every case the differences of the ordinates of the other two curves, such a curve would represent, by its ordinate at any point, the recoil or the stretch of the piece over and above the permanent set ; and this ordinate would, in the absence of further experiment, appear to represent the amount it would stretch if the load were removed and immediately applied again, over and above that part of the stretch which did not disappear on the removal of the load. The modulus of elasticity computed by means of the elongation above described, considered as the elongation of the piece, has been given the name "special modulus of elasticity" by Col. Rosset of the arsenal at Turin ; and he has called attention to the fact, that in the case of wrought-iron,

and also of steel, this special modulus of elasticity is nearly constant, even though the load applied be far above the limit of elasticity.

This can be graphically shown from the fact that the third of the above-mentioned curves, if plotted, will be nearly a straight line almost up to the point of fracture in the case of wrought-iron and steel.

#### EXAMPLES.

1. Plot the curves referred to above, for Hodgkinson's test of a wrought-iron rod 50 feet long, recorded on p. 353.
2. Do the same for the table of experiments on cast-iron bars 10 feet long, recorded on p. 339.

#### WROUGHT-IRON BOILER-PLATE.

Some tests of iron boiler-plate have already been quoted; viz., Kirkaldy's. Some tables of tests made by Mr. C. B. Richards, and recorded in the "Transactions of the American Society of Civil Engineers," vol. ii., will next be given.

In these tables, L denotes that they were pulled lengthwise of the fibre, and C crosswise.

Long specimens are those whose smallest area of cross-section had a length of from 3 to 5 inches.

Short specimens are those whose smallest area of cross-section had no length.

| No. of Specimen. | Kind of Iron.                   | Nominal Shape of Specimen. | Direction of Lamination. | Approximate Dimensions of Original Section. | Tensile Strength per Square Inch of Original Cross-Section. |                   |               | Resistance per Square Inch of Fractured Area. | Contraction of Area, %. |

| 337      | "                              | 1.000                | —                  | 63547                             | 88025           | —  | 28                             | —                              |

Perhaps it ought to be stated that the boiler-plate tested and recorded in the first of these tables is boiler-plate of good quality in every case.

#### BRANDS OF PLATES.

The only safe way, in ordering plates for a boiler, as in ordering iron for any construction, is to prescribe the tests which it shall stand, as the same brands are used by different makers to denote very different qualities of iron.

As a rule, better iron will be obtained by purchasing at a mill where only superior qualities are manufactured, rather than at mills where all qualities are made.

In England the brands are very various, but are often graded "Best," "Best Best," and "Treble Best," the "Best" being the poorest of the three.

In the United States these brands are not used, and the usage varies with different mills. Some years ago the brands manufactured were as follows:—

1°. *Tank-Iron*, the lowest grade, not suitable for use in the shell of a boiler, and including all iron too poor for this purpose.

2°. *C. No. 1*.—This used to denote iron made by using only charcoal in the blast-furnace; and it furnished a good grade of iron, suitable to use in those parts of the shell of a steam-boiler which do not come in contact with the fire, and which do not have to be flanged.

3°. *C. H. No. 1*, or charcoal-hammered No. 1, which was also a charcoal iron, but was obtained by more working than C. No. 1, and was hence a better grade of iron.

4°. *Fire-box Iron*, suitable to use for sheets exposed to the fire.

5°. *Flange Iron*, or such as will flange without cracking.

These brands partly remain to-day, but they no longer bear the same meanings. Indeed, the name "C. H. No. 1" is, in many mills, given to iron in the manufacture of which no charcoal has been used.

There are a number of mills that use the following brands for boiler-plates; viz.,—

|               |                        |
|---------------|------------------------|
| Tank-Iron.    | Extra Flange.          |
| Refined Iron. | Shell Fire-Box.        |
| Shell Iron.   | C. H. No. 1 Fire-Box.  |
| C. H. No. 1.  | Extra Flange Fire-Box. |

Nevertheless, if we buy any one of these grades at different mills, we have no certainty of obtaining the same quality of iron; and, moreover, there are other mills that use different brands. "Refined iron," for instance, is a term that includes a

large number of qualities, beginning at much too low a grade to put in a boiler-shell.

The only sure way to secure good iron is to prescribe the tests it shall stand: i.e., the tensile strength, which should be over 45000 or 46000 lbs.; the limit of elasticity, which should be as much as 27000 or 28000 lbs.; the contraction of area at fracture, which should be at least 30 per cent. It should also stand bending double cold, red-hot, and at a flanging heat. It would be well to test also the soundness of the plates by punching them.

#### BRANDS OF BARS AND SHAPES.

For these, each mill has its own peculiar brands, to which it attaches its own signification. The only way to secure iron of whose quality we are sure, is, therefore, to require that it shall stand the suitable tests before being accepted.

#### COMPRESSIVE STRENGTH OF WROUGHT-IRON.

As far as the compressive strength of short cylinders of wrought-iron is concerned, we have hardly any direct experimental evidence; because the iron, especially if it is soft, will gradually flatten out, and not give way by suddenly breaking. The evidence furnished by Fairbairn's experiments on transverse strength of wrought-iron goes to show that the tensile and the crushing strength are nearly equal, though the earlier experiments of Fairbairn had given a less value for the crushing than for the tensile strength; and for a long time the crushing-strength of wrought-iron has been given as 36000 lbs. per square inch, which value is still to be found in Gordon's formula for the strength of wrought-iron columns.

Leaving this matter to be explained under the head of "Transverse Strength of Wrought-Iron," we will next proceed to consider the strength of wrought-iron columns.

§ 223. **Wrought-Iron Columns.** — Until a very recent date, we have had no experimental knowledge on this subject beyond the experiments of Hodgkinson, which have furnished the constants for Hodgkinson's, and also for Gordon's, formula, as already given in § 209 and § 211.

These formulæ have been in very general use, and it is only very recently that we have been able to test their accuracy by tests on full-size wrought-iron columns. The disagreement of the formulæ already referred to, with the results of the tests, has led to the proposal of a large number of similar formulæ, each having its constants determined to suit a certain definite set of tests, and hence all these formulæ thus proposed must be classed as empirical formulæ, and can only be applied with safety within the range of the cases experimented upon.

A number of these will now be enumerated: and then will follow tables of the actual tests, which furnish the best means of determining the strength of these columns; and it would appear that it is these tables themselves which the engineer would wish to use in designing any structure.

On the 15th of June, 1881, Mr. Clark, of the firm of Clark, Reeves, & Co., presented to the American Society of Civil Engineers a report of a number of tests on full-size Phoenix columns, made for them at the Watertown Arsenal, together with a comparison of the actual breaking-weights with those which would have been obtained by using the common form of Gordon's formula for wrought-iron,

$$\frac{P}{A} = \frac{36000}{1 + \frac{l^2}{36000\rho^2}},$$

where  $P$  = breaking-weight in lbs.,  $A$  = area of section in square inches,  $l$  = length in inches,  $\rho$  = least radius of gyration in inches. The table is as follows:—

| No. of Experiment. | Length of Column. | Ratio of Diameter to Length. | Weight. | Sectional Area. | Total Compression under Load. |            | Elastic Limit. |                       | Ultimate Strength. |                       | Total Ultimate Strength, in lbs. by Gordon's Formula. |
|--------------------|-------------------|------------------------------|---------|-----------------|-------------------------------|------------|----------------|-----------------------|--------------------|-----------------------|---|
|                    |                   |                              |         |                 | 20000 lbs.                    | 30000 lbs. | Total lbs.     | Lbs. per Square Inch. | Total lbs.         | Lbs. per Square Inch. |   |
| 1                  | ft. 28            | 42                           | 1142    | sq. in. 12.062  | 0.190                         | -          | -              | -                     | 424000             | 351.50                | 330146  |

On the other hand, if the breaking-weights of these columns were calculated from the formula

$$\frac{P}{A} = \frac{50000}{1 + \frac{l^2}{36000\rho^2}},$$

the results would be much nearer the actual results, though not very near. The Phoenix Company, in their handbook, give, for the strength of their columns,

$$\frac{P}{A} = \frac{50000}{1 + \frac{l^2}{3000h^2}},$$

where  $h$  = diameter in inches.

The set of tests above referred to, gave rise to considerable discussion, and the proposal of several modified forms of Gordon's formula, as well as other formulæ, which should agree more nearly with the results of the tests.

Mr. Bouscaren proposes the formula

$$\frac{P}{A} = \frac{38000}{1 + \frac{l^2}{100000\rho^2}},$$

and claims that this furnishes a very good degree of coincidence with the facts.

Mr. Theodore Cooper proposes, instead, a modified form of Gordon's formula, as follows :—

$$\text{For square-ended columns . . . } \frac{P}{A} = \frac{f}{1 + \frac{\left(\frac{l}{\rho} - 80\right)^2}{18000}}.$$

$$\text{For pin-ended columns . . . . } \frac{P}{A} = \frac{f}{1 + \frac{\left(\frac{l}{\rho} - 33\right)^2}{18000}}$$

$$\text{For round-ended columns . . . } \frac{P}{A} = \frac{f}{1 + \left(\frac{l}{\rho}\right)^2 \frac{1}{18000}}$$

And he gives, for the values of  $f$ ,

For Phoenix columns . . . . .  $f = 36000$ .

For American Company's columns. . .  $f = 30000$ .

For box and open columns . . . . .  $f = 31000$ .

He deduces these values of  $f$  from some tests made in 1875 by Mr. Bouscaren, combined with those, already referred to, made at the Watertown Arsenal. The box and open columns were made of channel-bars and latticing. The tables or diagrams presented to justify all these formulæ will not be given here, but any one can find them in the "Transactions of the American Society of Civil Engineers" for 1882. Mr. C. E. Emery proposed, at the same meeting, the formula

$$\frac{P}{A} = \frac{355063 + 30950x}{x + 6.175}$$

for the Phoenix columns tested, where  $x$  = number of diameters in the length.

Professor Burr proposes

$$\frac{P}{A} = \frac{42000 \left[ 1 + \log_e \left( 1 + \frac{\rho}{l} \right) \right]}{1 + \frac{1}{50000} \frac{l^2}{\rho^2}}$$

Professor Merriman proposes

$$\frac{P}{A} = \frac{37200}{1 + \frac{1}{158500} \frac{l^2}{\rho^2}}.$$

The above are the formulæ evoked from the discussion on the set of tests of Phoenix columns above referred to.

In the "Report of Progress of Work of the Cincinnati Southern Railway," by Thomas D. Lovett (Nov. 1, 1875), is given an account of some tests made on full-size wrought-iron columns. He concludes that the formula

$$\frac{P}{A} = \frac{f}{1 + a' \frac{l^2}{\rho^2}}$$

will give results agreeing fairly well with the facts, provided we use

$$\text{For flat ends. . . . . } a' = \frac{1}{36000},$$

$$\text{For flat at one end and round at the other, } a' = \frac{2}{36000},$$

and for  $f$  we put the crushing-strength of the iron per square inch.

On the other hand, Professor Burr deduces from these same tests the following formulæ (see Burr's "Elasticity and Resistance of Materials," p. 441):—

KEYSTONE COLUMNS.

$$\text{Flat ends (swelled columns) . . . } \frac{P}{A} = \frac{36000}{1 + \frac{l^2}{18300\rho^2}}$$

$$\text{Flat ends straight } \left\{ \begin{array}{l} \text{open} \\ \text{closed} \end{array} \right\} . . . \frac{P}{A} = \frac{39500}{1 + \frac{l^2}{18300p^2}}$$

$$\text{Pin ends swelled} . . . . . \frac{P}{A} = \frac{36000}{1 + \frac{l^2}{15000p^2}}$$

## SQUARE COLUMNS.

$$\text{Flat ends} . . . . . \frac{P}{A} = \frac{39000}{1 + \frac{l^2}{35000p^2}}$$

$$\text{Pin ends} . . . . . \frac{P}{A} = \frac{39000}{1 + \frac{l^2}{17000p^2}}$$

## PHOENIX COLUMNS.

$$\text{Flat ends.} . . . . . \frac{P}{A} = \frac{42000}{1 + \frac{l^2}{50000p^2}}$$

$$\text{Round ends} . . . . . \frac{P}{A} = \frac{42000}{1 + \frac{l^2}{12500p^2}}$$

$$\text{Pin ends} . . . . . \frac{P}{A} = \frac{42000}{1 + \frac{l^2}{22700p^2}}$$

AMERICAN BRIDGE COMPANY'S COLUMNS.

$$\text{Flat ends. . . . . } \frac{P}{A} = \frac{36000}{1 + \frac{l^2}{46000\rho^2}}$$

$$\text{Round ends. . . . . } \frac{P}{A} = \frac{36000}{1 + \frac{l^2}{11500\rho^2}}$$

$$\text{Pin ends . . . . . } \frac{P}{A} = \frac{36000}{1 + \frac{l^2}{21500\rho^2}}$$

Professor Burr has also determined the values of  $f$  and  $a$  in the formula

$$\frac{P}{A} = \frac{f}{1 + a \frac{l^2}{\rho^2}}$$

which should agree most nearly with the different sets of experimental results. He has also done the same for the values of  $a$  and  $n$  in the formula

$$\frac{P}{A} = a \left( \frac{\rho}{l} \right)^n,$$

this latter being a modification of Euler's formula; and he claims that the latter gives results agreeing better with experiment than the former.

The tests made at the Watertown Arsenal will next be given, together with cuts showing the form of the columns; these being taken from the government report, Executive Document 12, 47th Congress, first session.

## LATTICE-COLUMNS AND CHANNEL-BARS FROM DETROIT BRIDGE AND IRON COMPANY.

## TABULATION OF EXPERIMENTS ON WROUGHT-IRON COLUMNS.

## LATTICED COLUMNS.

Columns with Pin Ends tested, with Pins Vertical; Channel-Bars spaced 8 Inches apart.

The following are the figures showing the columns of which the tests were recorded in the tables given above:—

1-8-1059-1060.

Latticing staggered  $\frac{1}{2}$  inch rhnds

1095-1096-1107-1108.

1109-117.

3-4-5-6-11-12-13-14.

1111-1112-1113-1114-1115-1116-1117-1118-1119-1120-1121  
1122-1123-1124-1125-1126-1127-1128-1129-1130-1131-1132.

7-8-9-10-15-16-28-29.

18-19-20-21.

conclusions ; and the formulæ proposed by the different persons who have deduced formulæ to cover special sets of values may be advantageously used for cases intermediate between those that have been experimented upon.

§ 224. **Transverse Strength of Wrought-Iron.** — In all probability wrought-iron owes its extensive introduction into construction as much or more to the efforts of Sir William Fairbairn than to any one else ; and while he was furnishing the means to Eaton Hodgkinson to make extensive experiments on cast-iron columns, and while he made experiments himself on cast-iron beams, which were in use at that time, he also carried on a large number of tests on beams built of wrought-iron, more especially those of tubular form, and those having an I or a T section, and made of pieces riveted together. In his book on the "Application of Cast and Wrought Iron to Building Purposes" he gives an account of a large number of these experiments, including those made for the purpose of designing the Britannia and Conway tubular bridges, a fuller account of which will be found in his book entitled "An Account of the Construction of the Britannia and Conway Tubular Bridges." In the first-named treatise he urges very strongly the use of wrought-iron, instead of cast-iron, to bear a transverse load.

Fairbairn tested a number of wrought-iron built-up beams with different thicknesses of upper and lower flange. The first results he obtained showed, that, unless the upper plates were made very much thicker than the lower, the beam would invariably give way by crippling at the top.

At first he concluded that the tensile strength of wrought-iron is greater than its compressive strength, and it has often been so regarded.

Subsequent experiments made by him, however, showed, that, if the iron of the upper flange were distributed in the form of cells, the areas of the cross-sections required in order to

render the beam equally liable to give way by tearing or by crushing, were as 12 to 11, or nearly equal; thus tending to show that the tensile and compressive strengths of wrought-iron are nearly equal, and that the reason of the crippling in the first experiments was, that the iron between the rivets acted like a column, and bent, instead of bringing into play the entire compressive strength of the iron.

A summary of some of these first experiments, the details of which are in his "Application of Cast and Wrought Iron to Building Purposes," is given in the following table, taken from p. 116 of his book:—

| No. of Experiment. | Distance between Supports. | Depth, in inches. | Width, in inches. | Thickness of Top Plate. | Thickness of Bottom Plate. | Ultimate Deflection, in inches. | Breaking-weight, in lbs. | Manner of Failure. |

Very few tests have been made which claim to give the modulus of rupture of wrought-iron, for the reason that wrought-iron will bend very much before breaking when it is subjected to a transverse load.

Some experiments made on small pieces claim to show a modulus of rupture considerably in excess of the tensile or

compressive strength, while the few experiments that have been made for this purpose on full-size beams have given a modulus of rupture about equal to the tensile or compressive strength of the iron per square inch.

Of the experiments on deflection, however, we generally have a very uniform result shown for the modulus of elasticity, both from small and from large beams. As to experiments on large beams, besides those of Fairbairn, already referred to, we have:—

1°. Those made at the Watertown Arsenal by Mr. William Sooy Smith and by Col. Laidley.

2°. Some tests made for the Phoenix Iron Company, and recorded in their published handbook.

3°. Some tests made for the New-Jersey Iron and Steel Company, and recorded in their handbook.

Those made at the Watertown Arsenal are recorded in Executive Document 23, 46th Congress, second session, and were made merely on the deflections under moderate loads, and on the elastic limit. From those made on the deflections under moderate loads, the moduli of elasticity are deduced; and they agree very closely with the moduli of elasticity that are deduced from experiments on the tension of wrought-iron. Because those on the elastic limit do not agree with the tensile elastic limit of the outside fibre, does not seem to the writer to justify Mr. Smith in looking for some other element in the resistance besides the direct tensions and compressions recognized in the common theory.

The table of these results will now be given, and then the results obtained from some of the Iron Company's beams.

The experiments were made on T-beams with the flange upwards.

These tests give a higher modulus of elasticity than would seem advisable to use in the present state of our knowledge of the subject.

\* Average of 24 tests.

† Average of 25 tests.

The New-Jersey Iron and Steel Company give 12000 lbs. per square inch as the safe extreme fibre stress to be used in computing the safe load on any of their beams; and they claim, that, in so doing, they are using a factor of safety of four.

The rule which they give for computing deflections, on the other hand, corresponds to a modulus of elasticity of about 21000000 lbs. per square inch.

The Phoenix Company also give 12000 lbs. per square inch for extreme fibre stress, and claim, that, in so doing, they are using a factor of safety of about four. They give, for modulus of elasticity to be used in computing deflections, 24000000 lbs. per square inch.

Both companies claim to have had some of their beams tested, and that such tests support them in recommending the values given above.

Some of the tables of tests given in these handbooks will be placed here. The following table of tests, made for the New-Jersey Iron and Steel Company by a United-States government engineer, is given in their handbook; and it is stated that they are a few of the tests selected at random.

TESTS OF BEAMS OF NEW-JERSEY IRON AND STEEL COMPANY.

| Size of Beam.  | Clear Span, in feet. | How Loaded.                | Safe Load, in lbs., as given by the Company's Tables. | Load actually applied. | Ratio of Actual to Safe Load. | Effect on Beam.          | Calculated Deflection under Safe Load. | Actual Deflection under Safe Load. | Limit of Elasticity. Permanent Bending begins. |

Last load left on 15 minutes, deflection increasing to 2.965.

§ 225. **Steel.** — Steel is usually defined to be a compound of iron with a small percentage of carbon, this percentage varying from a very minute quantity up to one and a half, or at most two, per cent. Steel is made in one of the three following ways; viz., —

1°. By adding carbon to wrought-iron.

2°. By removing carbon from cast-iron.

3°. By melting together cast and wrought iron in suitable proportions.

These three processes are, as a rule, represented respectively by the following three kinds of steel: —

1°. Crucible steel,

2°. Bessemer steel,

3°. Open-hearth, or Siemens's Martin steel;

these being the three chief kinds that are made on the commercial scale.

*Crucible Steel.* — This should always be, and is by good makers, made by re-melting blister steel in crucibles; the latter being made by the cementation process, in which bars of wrought-iron are heated in contact with charcoal until they have absorbed the necessary amount of carbon.

Crucible steel is used for the finest cutlery, tools, etc., and wherever a very pure and homogeneous quality of steel is required.

*Bessemer Steel* is made by decarbonizing cast-iron by forcing a powerful blast through a mass of melted cast-iron, thus removing the greater part of its carbon, and then adding a small quantity of some very pure cast-iron which is rich in carbon, thus bringing up the percentage of carbon to the required amount.

*Open-hearth Steel* is made by fusing a charge consisting of the suitable proportions of cast-iron with wrought-iron scrap, or with Bessemer steel scrap.

Bessemer and open-hearth steel contain more impurities than crucible steel; but they are very much cheaper, and are just as suitable for many purposes. It is only in consequence of their introduction that steel can be extensively used on the large scale, as crucible steel would be too expensive for many purposes.

Steel is also made by puddling and by other processes.

Steel, unlike wrought-iron, is fusible; unlike cast-iron, it can be forged; and, with the exception of the higher grades, it can be welded, the welding of high-grade steel in large masses being a very uncertain operation, though small masses can be welded by taking proper care.

The special characteristic, however, is, that, with the exception of the lowest grades, when raised to a red heat and suddenly cooled, it becomes hard and brittle, and that, by subsequent heating and slow cooling, the hardness may be reduced to any desired degree. The first process is called hardening, and the second tempering.

Pure wrought-iron cannot be hardened by this means; and cast-iron can be hardened, but cannot be tempered.

*Case Hardening* is a process by which the outer coating of wrought-iron is turned into steel by heating it to a red heat in contact with bone-dust or some animal matter. This process gives the iron a hard surface combined with toughness.

Whereas the hardening element of steel should be only carbon, and whereas other substances should be absent as far as possible in the best steel, nevertheless phosphorus, silicon, and manganese, when present in small quantities, all have a hardening effect; and all these ingredients, and often sulphur, are generally found in Bessemer and open-hearth steel, sulphur, silicon, and phosphorus coming from the ore, the fuel, and the flux, and manganese being necessarily added, partly to counteract the effect of sulphur, partly, by its affinity for oxygen, to absorb any oxygen in the interior of the mass, and thus decrease the porosity, and partly to enable the steel to be welded by preventing the rapid oxidation of the surfaces at a high heat.

When Bessemer steel was first introduced, and for some time thereafter, it was chiefly used for rails. It is only since a more recent date that Bessemer and open-hearth steel have been made sufficiently homogeneous and reliable for use in construction generally; but at the present day it is displacing wrought-iron in many instances, as being more reliable, and it is likely to displace it even more.

In the construction of boilers, bridges, trusses, beams, etc., it will not do to use the higher grades of steel, but only the milder and more ductile kinds: thus steel with a tensile strength of more than 80000 or 90000 lbs. per square inch is generally too hard to use in construction; and for steam-boilers, if its strength exceed about 65000 lbs., it is liable to be too hard. It should also show a large percentage of contraction of area, as 30 per cent or upwards. Such steel contains but little carbon, generally not more than one-half per cent.

While there are a few isolated cases where it is claimed by some that the structure of iron or steel may be changed from fibrous to crystalline without over-heating, the greater part of the evidence tends to show, that, whenever crystallization has taken place, it has occurred at a temperature above a welding-heat; and in a great many instances where cold crystallization

has been claimed, it has been found on investigation that the piece has some time been over-heated.

Welding is a much more difficult operation in steel than in iron, as (1°) there is always danger of over-heating, and (2°) the metal does not unite as readily at a welding-heat; hence, in high grades of steel, welding is almost an impossibility, especially with large masses.

The injury done to steel plates by punching is greater than that done to iron plates: this injury can, however, be removed by annealing. Steel requires greater care in working it than iron, whether in punching, flanging, riveting, or other methods of working; otherwise it may, if over-heated, burn, or receive other injury from careless workmanship;

In regard to the term "temper," it should be observed, that by the steel-maker it is used to denote the percentage of carbon in the steel, a higher temper corresponding to a higher percentage of carbon. On the other hand, the term "temper" in common parlance refers to the degree of hardness as determined by tempering the steel.

The brands of steel are determined by each maker for himself, there being no uniformity in this regard.

The chemical composition of steel is one important element in its resisting properties; but, on the other hand, the mode of working also has a great influence on the quality.

The only means of securing good steel is, to prescribe the tests which it shall stand, and to reject all that does not fulfil the requirements.

Thus, good boiler-plate should have an ultimate strength of 55000 to 65000 lbs. per square inch, a limit of elasticity of about 30000 pounds, a contraction of area at fracture of about 30 per cent. It should not crack on (1°) being bent double cold, (2°) at a red heat, (3°) at a flanging-heat, and it should suffer but little injury by punching.

For other purposes, as in trusses, etc., it should be able to stand, without injury, the trials to which it has to be subjected

in construction, as bending, punching, riveting, etc. An account of the manner of applying such tests to angle irons, I-beams, etc., will be found in "Use of Steel for Constructive Purposes," by J. Barba.

*Effect of Temperature upon the Resisting Properties of Iron and Steel.* — The question of the effect of high and of low temperatures upon the resisting properties of iron and steel has been investigated by a number of different experimenters with seemingly discordant results. The following are the principal experimenters upon this subject :—

Sir William Fairbairn : Useful Information for Engineers.  
Committee of Franklin Institute : Franklin Institute Journal.  
Knutt Styffe and Christer P. Sandberg : Iron and Steel.  
Kollman : Engineering, July 30, 1880.  
Massachusetts Railroad Commissioners : Report of 1874.

The existing evidence on the subject has been very carefully collated, and compared by graphical means, by Professor Thurston. Comparing all these results and conclusions, it would seem, that, starting at the ordinary temperatures, —

1°. A decrease of temperature increases the tensile strength of iron and steel, but decreases its ductility ; thus rendering it more brittle, and hence decreasing its resilience, or power of resisting shocks.

2°. An increase of temperature up to about 570° F. increases the tensile strength ; but at a straw heat or a pale blue, almost all irons and steels are very brittle.

3°. An increase of temperature above 570° decreases the tensile strength, but increases the ductility.

*Effect of Cold-Rolling on Iron and Steel.* — It has already been stated, p. 370, that it was discovered independently by Commander Beardslee and Professor Thurston, that if a load were gradually applied to a piece of iron or steel which exceeded its elastic limit, and the piece then allowed to rest, the elastic limit and the ultimate strength would thus be increased. This

may be accomplished with soft iron and steel by cold-rolling or cold-drawing, but cannot be taken advantage of in hard iron or steel.

Professor Thurston, who has investigated this matter at great length, and made a large number of tests on the subject, gives the following as the results of cold-rolling:—

| Increase in                                       | Per Cent.  |
|---|------------|
| Tenacity . . . . .                                | 25 to 40   |
| Transverse stress . . . . .                       | 50 to 80   |
| Elastic limit (tension, torsion, and transverse), | 80 to 125  |
| Elastic resilience . . . . .                      | 300 to 400 |
| Elastic resilience (transverse) . . . . .         | 150 to 425 |

He also says, in regard to the modulus of elasticity,—

“Collating the results of several hundred tests, the author [Professor Thurston] found that the modulus of elasticity rose, in cold-rolling, from about 25000000 lbs. per square inch to 26000000, the tenacity from 52000 lbs. to nearly 70000, the elastic limit from 30000 lbs. to nearly 60000 lbs.; and the extension was reduced from 25 to  $10\frac{1}{2}$  per cent.

“Transverse loads gave a reduction of the modulus of elasticity to the extent of about 1000000 lbs. per square inch, an increase in the modulus of rupture from 73600 to 133600, and reduction of deflection at maximum load of about 25 per cent. The resistance of the elastic limit was doubled, and occurred at a much greater deflection than with untreated iron.”

On the other hand, the two steel eye-bars referred to on p. 422 show a decrease of modulus of elasticity with increasing over-strain.

*Whitworth's Compressed Steel.*—Sir Joseph Whitworth produces steel of great strength by applying to the molten metal, directly after it leaves the furnace, a pressure of about 14000 lbs. per square inch; this being sufficient to reduce the length

of an eight-foot column by one foot. He claims, according to D. K. Clark, to be able to obtain with certainty a strength of 40 English tons with 30 per cent ductility, and mild steel of a strength of 30 English tons with 33 or 34 per cent ductility.

The following table is taken from D. K. Clark's "Rules and Tables:" —

|   | Ultimate Tensile Strength, in lbs., per Square Inch. | Elongation, per cent. |
|---|--|-----------------------|
| Axles, boilers, connecting-rods, rivets, railway tires, guns, and gun-carriages, }                        | 89600  | 32                    |
| Cylinder linings, parts of large machines, hoops, and trunnions, }  | 107520   | 24                    |
| Large planing and lathe tools, shears, smiths' punches, dies and sets, cold-chisels, screw tools, etc., } | 129920   | 17                    |
| Boring-tools, finishing-tools for planing and turning, }  | 152320   | 10                    |
| Alloyed with tungsten . . . . .   | 161280   | 14                    |

§ 226. **Tensile Strength of Steel.** — The older experiments on the strength of steel are of but little value; as we have very imperfect records of the kind of steel used in the tests, and its mode of manufacture. Hence only the more recent experimenters will be enumerated.

Sir William Fairbairn: Useful Information for Engineers.

David Kirkaldy: (a) Experiments on Wrought-Iron and Steel.

(b) An Experimental Inquiry into the Strength of Fagersta Steel.

W. E. Woodbridge: Report on the Mechanical Properties of Steel, Chiefly with Reference to Gun Construction on the Woodbridge System.

Government Machine: (a) Executive Document 23, 46th Congress, 2d session.

(b) Executive Document 5, 48th Congress, 1st session.

J. Barba: The Use of Steel for Constructive Purposes. By J. Barba.

Tests made for St. Louis Arch : Woodward's History of the St. Louis Arch.

Tests of Steel for the Brooklyn Bridge : Roebling's Report of the Brooklyn Bridge.

Charles B. Dudley : Franklin Institute Journal, 1881.

A. F. Hill : Proceedings of the Engineers' Society of Western Pennsylvania, vol. i.

Professor R. H. Thurston : Materials of Engineering.

The following are the summaries of Kirkaldy's tests on steel bars and steel plates as given in his book, "Experiments on Wrought-Iron and Steel," published in 1866, giving the tensile strength and contraction of area of such specimens as he tested :—

## STEEL BARS.

These tests were made before the use of steel in construction had become as general as it has at the present day.

The quality and strength of steel are affected very seriously by its chemical composition. In this regard we have the record of a series of tests made by the Committee on Chemical Research of the United-States Government Commission, and recorded in Executive Document 23, 46th Congress, second session.

The following summary of this report will be appended here, giving only the percentages of the most important ingredients besides the iron. This summary is as follows :—

| Laboratory Number.<br>3 Samples of Each. | Average Elastic Limit,<br>in lbs., per Sq. In. | Average Modulus of<br>Elasticity. | Average Breaking-<br>Strength per Sq. In.<br>of Original Area. | Average Breaking-<br>Strength per Sq. In.<br>of Fractured Area. | Chemical Analysis.   |                      |            |            |             |            |
|--|--|-----------------------------------|--|---|--|----------------------|------------|------------|-------------|------------|
|  |  |                                   |  |   | Combined<br>Carbon.  | Graphitic<br>Carbon. | Silicon.   | Sulphur.   | Phosphorus. | Manganese. |
| 1518                                     | 21600  | 24648000                          | 37933  | 96033   | %<br>0.246   | %<br>0.011           | %<br>0.145 | %<br>0.004 | %<br>0.014  | %<br>0.020 |

Mr. A. F. Hill, in the "Transactions of the Engineers' Society of Western Pennsylvania" for 1880, gives an account of some tests of open-hearth steel manufactured by Anderson & Co. of Pittsburgh, taken from different runs, and ranging from 0.3 to 0.5 per cent of carbon; the steel being tested both in the form of specimens, and also in the form of eye-bars, plates, and riveted plate-girders.

The following account of some of these tests is condensed from his paper:—

L SPECIMEN TESTS OF BAR-ENDS 30 INCHES LONG, DESIGNED FOR EYE-BARS.

| Mark, and Carbon Percentage.            | Tensile Stress per Square Inch at         |  | Stretch at Fracture, %.              | Reduction of Area at Fracture, %. |

### II. EXPERIMENTS ON STEEL EYE-BARS WITH 0.3% CARBON.

Dimensions: Stem, 3 in.  $\times$   $\frac{1}{4}$  in.  $\times$  10 ft. Head,  $1\frac{1}{4}$  in. thick,  $7\frac{1}{2}$  in. across the eye.  
Pin-hole,  $3\frac{3}{8}$  in. diameter.

In those marked "upset," the bars were rolled to the required section of the stem, with sufficient surplus of length to form the heads by hydraulic upsetting.

In those marked "rolled," the heads were rolled by Klobman's patent process.

In those marked "welded," the heads were formed by welding pieces, and die forging.

Fractures of B1, B2, B3, F2, and F3 were fine, silky, and wedge-shaped.

F1 broke in head, and showed effect of over-heating; fracture coarse and granular.

A1, A2, and A3 broke in stem close to neck; fracture close-grained, 50 per cent granular, and showing effect of welding

heat. Weld was defective at junction of head and neck on account of welding-pieces having been too small.

Mr. Hill draws from these tests the following conclusions :—

1°. "The strength of the specimen exceeds, in each case, that of the manufactured bar."

2°. "The uniformity of the results obtained from the tests of the bar-ends shows conclusively that whatever difference in strength there is between these bar-ends and the manufactured eye-bar is properly ascribable to the mode of manufacture."

3°. "The results obtained from the rolled and the upset eye-bars approach nearest to the original bar strength, and give the best results. The difference between the results from these two methods is so trifling—and if any thing in the 0.3 per cent carbon group, slightly in favor of the upset bar—that it leaves no doubt in my mind that these two processes are equally good."

4°. "The results from the welded bars show, that, while steel can be perfectly welded, there is a loss of nearly 30 per cent of ultimate strength as compared with the original bar; moreover, the elastic limit is, too near the ultimate strength, and the percentage of elongation too small, to give sufficient warning of impending failure."

"It will, therefore, be safe to conclude that welded members in steel construction, while no worse than welded iron ones, are not desirable, and, in fact, ought not to be admitted at all, except where the grade of steel used is very low; and then the greatest caution in working and annealing will be required."

Mr. Hill states also that his experiments with eye-bars containing 0.5 per cent carbon bear out these conclusions.

*Tests of Steel Eye-Bars made on the Government Machine.*—In Executive Document No. 5, 48th Congress, first session, is the record of the tests of six eye-bars of steel, presented by the president of the Keystone Bridge Company.

The following is an extract from the report in regard to these eye-bars :—

"The eye-bars were made of Pernot open-hearth steel, furnished by the Cambria Iron Company of Johnstown, Penn.

"The furnace charges, about 15 tons each of cast-iron, magnetic ore, spiegeleisen, and rail-ends, preheated in an auxiliary furnace, required six and one-half hours for conversion.

"All these bars were rolled from the same ingot.

"Samples were tested at the steel-works taken from a test ingot about one inch square, from which were rolled  $\frac{3}{4}$ -inch round specimens.

"The annealed specimen was buried in hot ashes while still red-hot, and allowed to cool with them.

"The following results were obtained by tensile tests :—

|   | Elastic Limit, in lbs., per Sq. In. | Ultimate Strength, in lbs., per Sq. In. | Contraction of Area. | Modulus of Elasticity. | Carbon. |
|---|-------------------------------------|---|----------------------|------------------------|---------|
| $\frac{3}{4}$ -inch round rolled bar .                    | 48040                               | 73150                                   | %.                   | 28210000               | %.      |
| $\frac{3}{4}$ -inch round rolled and annealed bar . . . . | 42210                               | 69470                                   | 54.2                 | 29210000               | 0.27    |

"The billets measured 7 inches by 8 inches, and were bloomed down from 14-inch square ingot.

"They were rolled down to bar-section in grooved rolls at the Union Iron Mills, Pittsburgh.

"The reduction in the roughing-rolls was from 7 inches by 8 inches to  $6\frac{1}{4}$  inches by 4 inches ; and in the finishing-rolls, to  $6\frac{1}{2}$  inches by 1 inch.

"The eye-bar heads were made by the Keystone Bridge Company, Pittsburgh, by upsetting and hammering, proceeding as follows :—

"The bar is heated bright red for a length of (approximately) 27 inches, and upset in a hydraulic machine ; after

which the bar is reheated, and drawn down to the required thickness, and given its proper form in a hammer-die.

"The bars are next annealed, which is done in a gas-furnace longer than the bars. They are placed on edge on a car in the annealing-furnace, separated one from another to allow free circulation of the heated gases. They are heated to a red heat, when the fires are drawn, and the furnace allowed to cool. Three or four days, according to conditions, are required before the bars are withdrawn.

"The pin-holes are then bored.

"The analyses of the heads before annealing were:—

|                             |                 |
|-----------------------------|-----------------|
| "Carbon, by color . . . . . | 0.270 per cent. |
| Silicon . . . . .           | 0.036 "         |
| Sulphur . . . . .           | 0.075 "         |
| Phosphorus . . . . .        | 0.090 "         |
| Manganese . . . . .         | 0.380 "         |
| Copper . . . . .            | Trace.          |

"The bars were tested in a horizontal position, secured at the ends, which were vertical.

"To prevent sagging of the stem, a counterweight was used at the middle of the bar.

"Before placing in the testing-machine, the stem from neck to neck was laid off into 10-inch sections, to determine the uniformity of the stretch after the bar had been fractured.

"A number of intermediate 10-inch sections were used as the gauged length, obtaining micrometer measurements of elongation, and the elastic limit for that part of the stem which was not acted upon during the formation of the heads. Elongations were also measured from centre to centre of pins, taken with an ordinary graduated steel scale.

"The moduli of elasticity were computed from elongations taken between loads of 10000 and 30000 lbs. per square inch, deducting the permanent sets.

"The behavior of bars Nos. 4582 and 4583, after having been strained beyond the elastic limit, is shown by elongations of the gauged length measured after loads of 40000 and 50000 lbs. per square inch had been applied; and with bar No. 4583, after its first fracture under 64000 lbs. per square inch, a rest of five days intervening between the time of fracture and the time of measuring the elongations.

"Considering the behavior between loads of 10000 and 30000 lbs. per square inch, we observe the elongations for the primitive readings are nearly in exact proportion to the increments of load.

"Loads were increased to 40000 lbs. per square inch, passing the elastic limit at about 37000 lbs. per square inch; the respective permanent stretch of the bars being 1.31 and 1.26 per cent.

"Elongations were then immediately redetermined, which show a reduction in the modulus of elasticity, as we advanced with each increment, of 5000 lbs. per square inch.

"Corresponding measurements after the bars had been loaded with 50000 lbs. per square inch reach the same kind of results.

"The first fracture of bar No. 4583, under 64000 lbs. per square inch, occurred at the neck, leaving sufficient length to grasp in the hydraulic jaws of the testing-machine, and continue observations on the original gauged length. This was done after the fractured bar had rested five days.

"The elongations now show the modulus of elasticity constant or nearly so, the only difference in measurements being in the last figures, up to 50000 lbs. The readings were then immediately repeated, and the same uniformity of elongations obtained.

"An illustration of the serious influence of defective metal in the heads is found in the first fracture of bar No. 4583.

"There was about 27 per cent excess of metal along the line of fracture over the section of the stem."

TABULATION OF STEEL EYE-BAR TESTS.

| Number of Test. | Length, in inches. | Gauged Length, in inches. | Width, in inches. | Thickness, in inches. | Elastic Limit, in lb., per Square Inch. | Ultimate Strength, in lb., per Square Inch. | Elongation, per cent. |                           | Contraction of Area, per cent. | Modulus of Elasticity. | Maximum Compression on Pin-Holes, in lb., per Square Inch. | Position of Fracture. | Appearance of Fracture.           |

STEEL PLATES.

Steel plates are used in making plate-girders and other forms for resisting load, and also for steam-boilers.

For the latter purpose the steel must be very low in carbon, and must stand very much more in the way of bending, punching, shearing, etc., than in the former case. Its tensile strength will not be high, but it must have great ductility. The first set of tests to which reference will be made is the set given in Mr. Hill's paper already referred to, this steel being too high to be suitable for boiler-work.

He had made 54 tests of rolled open-hearth steel plates.

The following 15 tests give the relative strengths of the plates, and the percentages of carbon.

The plates tested were all  $\frac{3}{8}$  inch thick, 12 inches wide, and 6 feet long, tested as they came from the rolls; crop ends sheared, 50 inches between jaws of machine.

| 0.5                  | Punched and annealed . . . . .   | 57960                                | 84900    |

From these tests he draws the following conclusions :—

1°. "That both shearing and punching are injurious to all grades of steel, and cold punching far more than shearing."

2°. "That both these operations affect the elastic limit far more than they do the ultimate strength."

3°. "That apparently the lower grades of steel are more injured than higher grades ; but the evidence on this point is not certain, as the lower-grade plates were thicker than those of higher grade."

## TRANSVERSE STRENGTH OF STEEL.

A number of tests of the transverse strength of small bars of steel 1 or 2 inches square have been made by Kirkaldy and others; and they have generally shown a modulus of rupture larger than the tensile strength of the steel, frequently 1.5 times the tensile strength.

It is only now that the attempt is being made to roll steel I-beams, and thus far no tests have been made on full-size steel beams. Before we can decide upon the value of the modulus of rupture suitable to use, we need such tests; and it would not be safe to assume for these beams the constants deduced from the small ones. The steel used may vary greatly from a very mild to a very hard steel. It is probable that it will be a mild steel that will be used for beams.

Until we have experiments upon full-size beams, it would hardly be safe to use, for modulus of rupture, much more than would hold for an iron beam, or from 50000 to 60000 or 70000 lbs. per square inch.

§ 227. **Factor of Safety.**—In order to determine the proper dimensions of any loaded piece, it becomes necessary to fix, in some way, upon the greatest allowable stress per square inch to which the piece shall be subjected.

The most common practice has been to make this some fraction of the breaking-strength of the material per square inch.

As to how great this factor should be, depends upon —

- 1°. The use to which the piece is to be subjected;
- 2°. The liability to variation in the quality of the material;
- 3°. The question whether we are considering, as the load upon the piece, the average load, or the greatest load that can by any possibility come upon it;
- 4°. The question as to whether the structure is a temporary or a permanent one;

5°. The amount of injury that would be done by breakage of the piece;  
and other considerations.

The factors most commonly recommended are, 3 for a dead or quiescent load, and 6 for a live or moving load.

The American and English practice in the case of iron bridges is to use a factor of safety of 4 for both dead and moving load. In machinery a factor as large as 6 is desirable when there is no liability to shocks; and when there is, a larger factor should be used.

A method very rarely followed for tension and compression pieces is, to prescribe that the stretch under the given load should not exceed a certain fixed fraction of the length. This requires a knowledge of the modulus of elasticity of the material.

In the case of a piece subjected to a transverse load, it is the most common custom to determine its dimensions in accordance with the principle of providing sufficient strength; and for this purpose a certain fraction (as one-fourth) of the modulus of rupture is prescribed as the greatest allowable safe stress per square inch at the outside fibre. Thus, the two iron companies already referred to prescribe 12000 lbs. per square inch as the greatest allowable stress at the outside fibre for wrought-iron beams, this being about one-fourth of the modulus of rupture.

The other method for dimensioning a beam is, to prescribe its stiffness; i.e., that it shall not deflect under its load more than a certain fraction of the span. This fraction is taken as  $\frac{1}{400}$  to  $\frac{1}{800}$ .

This latter method depends upon the modulus of elasticity of the beam; and while it is the most advisable method to follow, and as a rule would be safer than the other method, nevertheless, in the case of very stiff and brittle material it might be dangerous: hence we ought to know also the break-

ing-weight and the limit of elasticity of the beam we are to use, and not allow it to approach either of these. This precaution will be especially important to observe in the case of steel beams, which are only now being introduced.

On the other hand, in moving machinery a factor of safety of six is usually required when there is no unusual exposure to shocks, as in smooth-running shafting, etc.; and when there are irregular shocks liable to come upon the piece, a greater factor is used.

§ 228. **Wöhler's Results.** — The extensive experiments of Wöhler for the Prussian government, which were subsequently carried on by his successor, Spangenberg, were made to determine the effect of oft-repeated stresses, and of changes of stress, upon wrought-iron and steel.

In the ordinary American and English practice, it is customary, in determining the dimensions of a piece, as of a bridge member, to ascertain the greatest load which the piece can ever be called upon to bear, and to fix the size of the piece in accordance with this greatest load.

Wöhler called attention to the fact that the load that would break a piece depends upon both the greatest and least load that it would ever be called upon to bear. Thus, a tension-rod which is subjected to alternate changes of load extending from 20000 to 80000 lbs. would require a greater area for safety than one which was subjected to loads varying only between the limits of 60000 and 80000 lbs.; and this would require more area than one which was subjected to a steady load of 80000 lbs.

Wöhler expresses this law as follows, in his "*Festigkeitsversuche mit Eisen und Stahl.*"

"The law discovered by me, whose universal application for iron and steel has been proved by these experiments, is as follows: The fracture of the material can be effected by variations of stress repeated a great number of times, of

which none reaches the breaking-limit. The differences of the stresses which limit the variations of stress determine the breaking-strength. The absolute magnitude of the limiting stresses is only so far of influence as, with an increasing stress, the differences which bring about fracture grow less.

“For cases where the fibre passes from tension to compression and *vice versa*, we consider tensile strength as positive and compressive strength as negative; so that in this case the difference of the extreme fibre stresses is equal to the greatest tension plus the greatest compression.”

Besides the ordinary tests of tensile, compressive, shearing, and torsional strength, he made his experiments mainly on the following two cases:—

1°. Repeated tensile strength; the load being applied and wholly removed successively, and the number of repetitions required for fracture counted.

2°. Alternate tension and compression of equal amounts successively applied, the number of repetitions required for fracture being counted.

In making these two sets of tests, he made the first set in two ways:—

(a) By applying direct tension.

(b) By applying a transverse load, and determining the greatest fibre stress.

The second set of tests was made by loading at one end a piece of shaft fixed in direction at the other, and then causing it to revolve rapidly, each fibre passing alternately from tension to an equal compression, and *vice versa*.

He also tried a few experiments where the lower limit of stress was neither zero nor equal to the upper limit, with a minus sign, also some experiments on torsion, on shearing, and on repeated torsion.

When Wöhler had made his experiments, and published his results, there were a number of attempts made by different

persons to deduce formulæ which should depend upon these experiments for their constants, and which should serve to determine the breaking-strength for any given variation of stresses.

Only two of these formulæ will be given here, viz., —

1°. That of Launhardt for one kind of stress,

2°. That of Weyrauch for alternate tension and compression, as these are the most used of the formulæ developed.

#### LAUNHARDT'S FORMULA.

The constants used in this formula are —

1°.  $t$ , the carrying-strength of the material per unit of area; this being the greatest load per square inch of which the piece can bear an unlimited application without breaking. Practically it is the breaking-strength per unit of area.

2°.  $u$ , the primitive safe strength; i.e., the greatest stress per unit of area of which the piece can bear, without breaking, an unlimited number of repetitions, the load being entirely removed between times. It is not a *safe* but a *breaking* strength. These two quantities have been determined experimentally by Wöhler; and it is the object of Launhardt's formula to deduce, in terms of  $t$ ,  $u$ , and the ratio between the greatest and least loads to which the piece is ever subjected, the value  $a$  of the breaking-strength per unit of area when these loads are applied.

The formula and its deduction are as follows: —

Let the greatest stress per unit area be  $a$ .

the least stress per unit area be  $c$ .

their difference be  $d = a - c$ .

Now  $a$  depends on  $d$  for its value; and hence we may write

$$a = ad,$$

where  $a$  is a function of  $a$  also.

Now, the two cases experimented upon, viz., —

$$\begin{array}{lll} 1^{\circ}. \text{ When } a = t, & c = t, & d = 0, \\ 2^{\circ}. \text{ When } a = u, & c = 0, & d = u, \end{array}$$

must be satisfied by the value of  $a$  used: otherwise the value we use is wrong, as these are two particular cases. Now, Launhardt takes

$$a = \frac{t - u}{t - d},$$

and hence

$$a = \frac{t - u}{t - d}d; \quad (1)$$

and it will become evident that this value of  $a$  does satisfy the two conditions stated if we observe, that, in the first case, since

$$d = 0,$$

we must have  $a = \infty$  in order that we may have

$$a = t;$$

and if we put  $a = t$  in the value of  $a$ , we obtain

$$a = \infty :$$

also in the second case, since  $d = u$  and  $a = u$ , we must have

$$a = 1;$$

and if we put  $a = u$  in the value of  $a$ , we obtain

$$a = 1.$$

Hence in using (1) we are using a formula for  $a$  which satisfies the two cases of carrying-strength and of primitive safe strength; and the question as to its being a suitable value to use must depend upon how well it will satisfy intermediate values, i.e., cases where the two extremes are not those of the carrying-strength nor of the primitive safe strength.

In the few cases of intermediate values experimented upon by Wöhler, there is a very close agreement between the experimental results and those obtained by the formula.

Now, put  $d = a - c$  in (1), and we have

$$a = \frac{t - u}{t - a}(a - c) \quad (2)$$

$$at - a^2 = at - au - c(t - u)$$

$$\therefore a^2 = au + (t - u)c$$

$$\therefore a = u + (t - u)\frac{c}{a}; \quad (3)$$

and if we denote by  $\max L$  the greatest load on the entire piece, and by  $\min L$  the least, we shall have

$$\frac{c}{a} = \frac{\min L}{\max L}.$$

Hence

$$a = u + (t - u)\frac{\min L}{\max L}, \quad (4)$$

this being in such a form as can be used. Or we may write it thus :

$$a = u \left\{ 1 + \frac{t - u}{u} \frac{\min L}{\max L} \right\}, \quad (5)$$

this being the more common form.

The values of the constants as determined by Wöhler's experiments, and the resulting form of the formula for Phoenix axle-iron and for Krupp cast-steel, have already been given in § 172.

In the same paragraph are given the corresponding values of  $b$ , the safe working-strength, the factor of safety being three.

WEYRAUCH'S FORMULA FOR ALTERNATE TENSION AND  
COMPRESSION.

The constants used in this formula are :—

1°.  $u$ , the primitive safe strength, which has been already defined.

2°.  $s$ , the vibration safe strength ; i.e., the greatest stress per unit of area of which the piece can bear, without breaking, an unlimited number of applications, the other extreme stress which it bears alternately being  $-s$ .

He lets  $a$  = greatest stress per unit of area,  $c$  = greatest stress of the opposite kind per unit of area. If  $a$  is tension,  $c$  is compression, and *vice versa*.

Then, if  $d$  is the difference,

$$d = a + c.$$

Weyrauch writes, as before,

$$a = ad,$$

and gives to  $a$  a value which will satisfy the two special cases experimented upon ; viz., —

|                    |           |            |
|--------------------|-----------|------------|
| 1°. When $a = u$ , | $c = 0$ , | $d = u$ .  |
| 2°. When $a = s$ , | $c = s$ , | $d = 2s$ . |

He writes

$$a = \frac{u - s}{2u - s - a}$$

$$\therefore a = \frac{u - s}{2u - s - a} d. \quad (6)$$

This value of  $a$  satisfies the two special cases referred to ; for in the first case, since  $d = u$  and  $a = u$ , we must have  $a = 1$  ; and if we write  $a = u$  in the value of  $a$ , we obtain  $a = 1$ . Also in the second case, since  $d = 2s$  when  $a = s$ , we must have  $a = \frac{1}{2}$  ; and if we write  $a = s$  in the value of  $a$ , we obtain  $a = \frac{1}{2}$ .

This, however, has not been tested for intermediate values.

Now write  $d = a + c$  in equation (1), and we shall have

$$a = \frac{u - s}{2u - s - a}(a + c),$$

$$2au - as - a^2 = au - as + (u - s)c$$

$$\therefore a^2 = au - (u - s)c \quad (7)$$

$$\therefore a = u - (u - s)\frac{c}{a}; \quad (8)$$

and if we write

$$\frac{c}{a} = \frac{\max L'}{\max L},$$

where  $\max L$  = greatest load on the piece, and  $\max L'$  = greatest load of opposite kind, so that, if  $L$  is tension,  $L'$  shall be compression, and *vice versa*, we shall have

$$a = u - (u - s)\frac{\max L'}{\max L}, \quad (9)$$

this being in a form suitable to use, the more common form being

$$a = u \left\{ 1 + \frac{u - s}{u} \frac{\max L'}{\max L} \right\}. \quad (10)$$

The values of the constants as determined from Wöhler's experiments, and the resulting form of the formulæ for Phoenix axle-iron and for Krupp cast-steel, are given in § 176.

The above demonstrations of Launhardt's and of Weyrauch's formulæ are substantially those given in the translation of Weyrauch's "Structures of Iron and Steel," by Professor Dubois, the explanations being somewhat changed.

## GENERAL REMARKS.

In each case the value of  $a$  given by the formula (5) or (10) is the breaking-strength per unit of area for either tension or compression in Launhardt's formula; and in the case of Weyrauch's, the value of  $a$  is the breaking-strength per square inch of the same kind as  $\max L$ ; i.e., tension if this is tension, or compression if this is compression.

If either of these values of  $a$  be divided by 3, we have, according to Weyrauch, the safe working-strength.

If, now, the piece be a tension piece, its area will be found by dividing its greatest load by the safe working-strength; if, on the other hand, it be subjected to compression, and it be a short piece, its area will also be found by dividing the greatest compression by the safe working-strength per unit of area: but if it be a long column, and we wish to use Wöhler's results, we must merely use the value  $\frac{a}{3}$  as the safe working-strength per unit of area, and use this in whatever formula we may employ for calculating a column.

## WÖHLER'S EXPERIMENTAL RESULTS.

Wöhler himself made his tests upon the extremes of fibre stresses of which a piece could bear, without breaking, an unlimited number of applications. He gives, as a summary of these results, the following:—

In iron,—

|         |                         |     |                         |
|---------|-------------------------|-----|-------------------------|
| Between | +16000 lbs. per sq. in. | and | −16000 lbs. per sq. in. |
| "       | +30000                  | "   | "                       |
| "       | +44000                  | "   | "                       |

In axle-steel,—

|         |                         |     |                         |
|---------|-------------------------|-----|-------------------------|
| Between | +28000 lbs. per sq. in. | and | −28000 lbs. per sq. in. |
| "       | +48000                  | "   | "                       |
| "       | +80000                  | "   | "                       |

In untempered spring steel, —

| Between +50000 lbs. per sq. in. and |        |   |   | 0 | lbs. per sq. in. |   |
|-------------------------------------|--------|---|---|---|------------------|---|
| "                                   | +70000 | " | " | " | +25000           | " |
| "                                   | +80000 | " | " | " | +40000           | " |
| "                                   | +90000 | " | " | " | +60000           | " |

For shearing in axle-steel, —

| Between +22000 lbs. per sq. in. and |        |   |   | —22000 | lbs. per sq. in. |   |
|-------------------------------------|--------|---|---|--------|------------------|---|
| "                                   | +38000 | " | " | "      | 0                | " |

This table would justify the use, in Launhardt's and Weyrauch's formulæ, of the following values of  $u$  and  $s$ ; viz., —

In iron, —

$$u = 30000 \text{ lbs. per sq. in.,}$$

$$s = 16000 \text{ lbs. per sq. in.}$$

In axle steel, —

$$u = 48000 \text{ lbs. per sq. in.,}$$

$$s = 28000 \text{ lbs. per sq. in.}$$

In untempered spring steel, —

$$u = 50000 \text{ lbs. per sq. in.}$$

And it would require, that if, with these values of  $u$ , and the values of  $t$  given in §§ 172 and 176, we put

$$c = 24000$$

in Launhardt's formula for iron, we ought to obtain approximately

$$a = 44000;$$

and if we put  $c = 35000$  in that for steel, we should obtain approximately

$$a = 80000.$$

## FACTOR OF SAFETY.

We have seen that Weyrauch recommends, to use with Wöhler's results, a factor of safety of three for ordinary bridge work and similar constructions.

Wöhler himself, however, in his "*Festigkeits versuche mit Eisen und Stahl*," says, —

1°. That we must guard against any danger of putting on the piece a load greater than it is calculated to resist, by assuming as its greatest stress the actually greatest load that can ever come upon the piece; and

2°. This being done, that the only thing to be provided for is the lack of homogeneity in the material.

3°. That any material which requires a factor of safety greater than two is unfit for use. This advice would hardly be accepted by engineers, however.

He also claims that the reason why it is safe to load car-springs so much above their limit of elasticity, and so near their breaking-load, is, that the variation of stress to which they are subjected is very inconsiderable compared with the greatest stress to which they are subjected.

## GENERAL REMARKS.

It is to be observed, —

1°. The tests were all made on a good quality of iron and of steel, consequently on materials that have a good degree of homogeneity.

2°. The specimens were all small, and the repetitions of load succeeded each other very rapidly, no time being given for the material to rest between them.

3°. No observations were made on the behavior of the piece during the experiment before fracture.

4°. No experiments were made upon cast-iron and timber; and the results of such experiments, if made, could hardly be

expected to be of much value, as these materials are so lacking in homogeneity.

5°. As long as we are dealing only with tension, we can say without error that

$$\frac{e}{a} = \frac{\min L}{\max L};$$

but as soon as both stresses or either become compression, if the piece is long compared with its diameter, we cannot assert with accuracy that

$$\frac{e}{a} = \frac{\max L'}{\max L};$$

and hence results based on such an assumption must be to a certain extent erroneous.

6°. When a piece is subjected to alternate tension and compression, it must be calculated so as to bear either: thus, if sufficient area is given it to enable it to bear the tension, it may not be able to bear the compression unless the metal is so distributed as to enable it to withstand the bending that results from its action as a column.

#### EXAMPLES.

1. Determine the cross-section necessary for a wrought-iron tie where greatest load = 800000 lbs. and least load = 80000 lbs.
2. Determine the cross-section necessary for a wrought-iron strut to bear the same loads.
3. What is the greatest and what the least working-strength recommended by Wöhler for wrought-iron? What for steel? Compare with ordinary methods, using factor of safety of four.

§ 229. **Shearing-Strength of Iron and Steel.**—Some of the most common cases where the shearing resistance of iron and steel is brought into play are:—

- 1°. In the case of a torsional stress, as in shafting.

2°. In the case of pins, as in bridge-pins, crank-pins, etc.

3°. In the case of riveted joints.

In most cases the shearing is accompanied by tensions or compressions, or other stresses, and it is difficult to separate the effects; so that, in the present state of our knowledge, we cannot explain the fact, that, when the breaking shearing-strength of wrought-iron or steel is deduced from an experiment on torsional strength, it is found to be about equal to the tensile strength, while when deduced from experiments on riveted joints, it is found to be about  $\frac{3}{4}$  or  $\frac{1}{2}$  the tensile strength.

Experiments on this subject are to be found in —

1°. Steam-Boilers, by William H. Shock, U.S.N.

2°. Kirkaldy: Experimental Inquiry into the Properties of Fagersta Steel.

3°. A. B. W. Kennedy: Engineering. May 6, 1881.

In regard to cast-iron, Bindon Stoney found the shearing and tensile strength about equal.

As to shearing modulus of elasticity, Bauschinger's experiments on cast-iron give about two-fifths the tensile modulus of elasticity; and Wöhler's experiments gave for steel almost exactly two-fifths the tensile modulus, his value being 11236500 when the tensile modulus was 29600000. According to the theory of elasticity, the modulus of elasticity for shearing should be about two-fifths that for tension or compression, as will be shown later; and these experiments furnish a most beautiful confirmation of the theory of elasticity.

The cases where shearing comes in play in wrought-iron and steel will, therefore, be treated separately.

§ 230. Torsional Strength of Wrought-Iron and Steel. —

The most common custom for computing the strength of a shaft has been to use one based upon its twisting-moment; and hence using the shearing breaking-strength of the material, as determined from an experiment on simple torsion, for our con-

stant. It is generally the fact, however, that, when shafting is running, the pulls of the belts create a bending backwards and forwards, bringing the same fibre alternately into tension and compression; and this is combined with the shearing-stresses developed due to the twisting-moment alone. No tests have been made upon the effect of the combination of these stresses under working conditions; and until we have a systematic set of tests of this character, we shall not be able to predict with certainty the behavior of a shaft under working conditions. At the two extremes of these general cases are:—

1°. The case when the portion of a shaft between two hangers has no pulleys upon it, and when the pulls on the neighboring spans are not so great as to deflect this span appreciably. That is a case of pure torsion: and if the shaft is running smoothly, with no jars or shocks, and no liability to have a greater load thrown upon it temporarily, we should properly compute it by the usual torsion formula, given in § 212; and we may use for breaking-strength of wrought-iron and steel the tensile strength, and use a factor of safety no greater than six.

2°. The case when, pulleys being placed otherwise than near the hangers, the belt-pulls are so great that the torsion becomes insignificant compared with the bending, and then it would be proper to compute our shaft so as not to deflect more than  $\frac{1}{1200}$  of its span under the load, or better, not more than  $\frac{1}{1800}$ : of course we should compute also the breaking transverse load, and see that we have a good margin of safety.

In other cases, experiments upon shafting under working conditions are needed; as up to the present time all such matters have been decided in one of three ways, as follows:—

1°. By using the ordinary torsion formula combined with a large factor of safety.

2°. As recommended by D. K. Clark, by computing the shaft also for deflection, and providing that its deflection shall not exceed  $\frac{1}{1200}$  or  $\frac{1}{1800}$  of its span.

This, however, neglects the torsion, and also the rapid change of stress upon each fibre from tension to compression, and *vice versa*.

3°. By using the formula of Grashof or of Rankine for combined bending and shearing; but this has not had the constants worked out from a test on such combined stress, and it is seldom used.

In regard to experiments upon torsional strength, they are usually made by twisting a short piece of shaft until rupture occurs, measuring its twist under smaller loads, and from these computing the modulus of shearing elasticity.

Such tests have been made by —

- 1°. Kirkaldy: D. K. Clark's Rules and Tables.
- 2°. D. K. Clark: English Civil Engineers' Committee.
- 3°. Major Wade.
- 4°. United-States Board to test Iron and Steel: Executive Document No. 23, 46th Congress, 2d session.
- 5°. Professor Thurston: Materials of Engineering.

The general result has usually been, to obtain about the same shearing breaking fibre stress as the tensile strength of the material, and a modulus of elasticity about two-fifths the tensile modulus. Of course the values vary more or less, sometimes being greater and sometimes less than the values given above, according to the quality of the iron; so that we can determine by experiment only what any one iron will bear. None of these tests will be recorded here, but some of the rules in common use for figuring the strength will be given: they are merely some of the formulæ already referred to, with the constants changed.

Unwin gives the direction, —

- 1°. That the axle must be calculated as a beam to bear the weight of the pulley and the belt-pull that is to come upon it.

2°. For shafting transmitting power, and subject to torsion only, he gives

$$d = \alpha \sqrt[3]{PR} = \beta \sqrt[3]{\frac{HP}{N}},$$

where  $d$  = diameter in inches,  $PR$  = twisting-moment in inch-pounds,  $N$  = number of turns per minute,  $HP$  = number of horses-power to be transmitted; and he gives for  $\alpha$  and  $\beta$  the following values:—

|                        | $\alpha$ . | $\beta$ . |
|------------------------|------------|-----------|
| Wrought-iron . . . . . | 0.08275    | 3.294     |
| Cast-iron . . . . .    | 0.1042     | 4.150     |
| Steel . . . . .        | 0.0723     | 2.877     |

these values assuming for safe greatest fibre stress, for wrought-iron, 9000; for cast-iron, 4500; and for steel, 13500 lbs. per square inch.

3°. For the crank-shaft of a steam-engine he advises us to consider the maximum twisting-moment as 1.3 times the mean.

4°. For combined twisting and bending, he gives the Rankine formula, equation (2), § 215, and puts it in the following form:

$$d = \sqrt[3]{K + \sqrt{K^2 + 1}} \sqrt[3]{\frac{5.1}{f}} \sqrt[3]{T},$$

where  $d$  = diameter in inches,  $f$  = outside fibre breaking shear-strength per square inch,  $T$  = twisting-moment in inch-pounds,  $K = \frac{M}{T}$  = ratio of bending to twisting moment.

Then, calling

$$n = \sqrt[3]{K + \sqrt{K^2 + 1}},$$

$n$  will be the ratio of the diameter to be used, to the diameter needed to resist the torsion alone; and he gives, when

$$\begin{array}{cccccccccc} K = 0.25 & 0.50 & 0.75 & 1.00 & 1.25 & 1.50 & 1.75 & 2.00 & 3.00, \\ n = 1.09 & 1.17 & 1.26 & 1.36 & 1.42 & 1.49 & 1.56 & 1.62 & 1.83. \end{array}$$

For the propeller shaft of a steam-vessel, he advises to use

$$K = 0.25 \text{ to } 0.50 \quad \therefore n = 1.09 \text{ to } 1.17.$$

For line shafting in mills, he advises

$$K = 0.75 \text{ to } 1.00 \quad \therefore n = 1.26 \text{ to } 1.34.$$

For crank-shafts and heavy shafting subject to shocks,

$$K = 1.00 \text{ to } 1.50 \quad \therefore n = 1.34 \text{ to } 1.49.$$

5°. For forged crank-shafts, he gives

$$d = 4.55 \sqrt[3]{\frac{HP}{N}}.$$

To control the deflection of shafting 10 or 11 feet between hangers, he gives

$$d = \left( \frac{L}{\gamma} \right)^{\frac{1}{3}},$$

where  $L$  = span in inches, and  $\gamma = 54$  to  $60$ .

Professor Thurston gives, —

For head shafts well supported against springing, —

$$\text{Wrought-iron, } d = \sqrt[3]{\frac{125HP}{N}}. \quad \text{Cold-rolled iron, } d = \sqrt[3]{\frac{75HP}{N}}.$$

For line-shafting, hangers 8 feet apart, —

$$\text{Wrought-iron, } d = \sqrt[3]{\frac{90HP}{N}}. \quad \text{Cold-rolled iron, } d = \sqrt[3]{\frac{55HP}{N}}.$$

For transmission simply, no pulleys, —

$$\text{Wrought-iron, } d = \sqrt[3]{\frac{62.5HP}{N}}. \quad \text{Cold-rolled iron, } d = \sqrt[3]{\frac{35HP}{N}}.$$

Mr. James B. Francis gives the following table for distance between bearings of shafting carrying no side strain :—

| Diameter. | Wrought-Iron. | Steel. | Diameter. | Wrought-Iron. | Steel. |
|-----------|---------------|--------|-----------|---------------|--------|
| in.       | ft.           | ft.    | in.       | ft.           | ft.    |
| 2         | 15.5          | 15.9   | 6         | 22.3          | 22.9   |
| 3         | 17.7          | 18.2   | 7         | 23.5          | 24.1   |
| 4         | 19.5          | 20.0   | 8         | 24.6          | 25.2   |
| 5         | 20.9          | 21.6   | 9         | 25.5          | 26.2   |

It should be observed, that it is only a mild steel that can be used for shafting, — steel of about 60000 lbs. tensile strength per square inch: hence the calculations cannot differ very greatly from those for wrought-iron.

§ 231. **Bridge-Pins.** — In the case of a bridge-pin or other pin, the shearing-stress is always accompanied by a very large element of bending; so that the principles of transverse strength come into play very largely, and perhaps in many cases wholly.

The rules for proportioning bridge-pins used by different engineers and constructors have been various, but have generally been founded upon the theory of transverse strength; for those given by Charles Bender, the student is referred to his treatise on "Bridge-Pins" (Van Nostrand's Science Series). No attempt will be made to give any of the rules used; but, inasmuch as there were quite a number of such pins tested at the Watertown Arsenal, there will be given a summary of the tests, which are to be found in detail in Executive Document 12, 47th Congress, first session. All the pins tested were of wrought-iron, and had semicircular seats at middle and ends.

From this table the modulus of elasticity can be figured, and the deflection of the pin under any given load and span;

or the table may be employed to interpolate, to find the sizes to be used without causing too much deflection.

| Diameter,<br>in inches. | Clear<br>Span. | Width<br>of<br>Middle<br>Bear-<br>ing. | Load nearest<br>one-half<br>Maximum<br>Load, in lbs. | Deflection,<br>in inches. | Maximum<br>Load ap-<br>plied, in lbs. | Deflection,<br>in inches. | Amount of<br>Indentation,<br>in inches. |
|-------------------------|----------------|--|--|---------------------------|---------------------------------------|---------------------------|---|
| 2.500                   | 24             | I                                      | 10000  | 0.0517                    | 20000                                 | 1.2700                    | 0.0070                                  |
| 2.497                   | 24             | I                                      | 8000   | 0.0420                    | 15000                                 | 0.3290                    | 0.0020                                  |
| 2.500                   | 18             | I                                      | 10000  | 0.0238                    | 21000                                 | 0.1660                    | 0.0025                                  |
| 2.500                   | 18             | i                                      | 10000  | 0.0248                    | 18000                                 | 0.1000                    | < 0.0010                                |
| 2.500                   | 12             | -                                      | 15000  | 0.0133                    | 30000                                 | 0.0367                    | 0                                       |
| 2.500                   | 12             | -                                      | 14000  | 0.0129                    | 27000                                 | 0.0437                    | < 0.0010                                |
| 2.500                   | 6              | I                                      | 33000  | 0.0066                    | 65000                                 | 0.0263                    | 0.0030                                  |
| 2.500                   | 6              | I                                      | 30000  | 0.0064                    | 60000                                 | 0.0184                    | -                                       |
| 3.000                   | 24             | -                                      | 11000  | 0.0278                    | 22000                                 | 0.1260                    | -                                       |

§ 232. **Riveted Joints.** — The most common way of uniting plates of wrought-iron or steel is by means of rivets. It is, therefore, a matter of importance to know the strength of such joints, and also the proportions which will render their efficiencies greatest; i.e., that will bring their strength as near as possible to the strength of the solid plate.

In § 177 was explained the mode of proportioning riveted joints usually taught, based upon the principle of making all the resistances to giving way equal, and assuming, as the modes of giving way, those there enumerated. This theory does not, however, represent the facts of the case, as —

1°. The stresses which resist the giving-way are of a more complex nature than those there assumed, so that the efficiency of a joint constructed in the way described above may not be as great as that of one differently constructed;

2°. The effects of punching, drilling, and riveting, come in to modify further the action; and

3°. The purposes for which the joint is to be used, often fix some of the dimensions within narrow limits beforehand.

In order to know, therefore, the efficiency of any one kind of joint, we must have recourse to experiment. And here again we must not expect to draw correct conclusions from experiments made upon narrow strips of plate riveted together with one or two rivets; but we need experiments upon joints in wide plates containing a sufficiently long line of rivets to bring into play all the forces that we have in the actual joint. The greater part of the experiments thus far made have been made upon narrow strips, with but few rivets, — there have been but few of the latter class of tests, — and no complete and systematic series of tests has thus far been carried out, though such a series has been begun on the government testing-machine at the Watertown Arsenal.

The only tests that will be quoted here, are: —

1°. The summary of the tests of this series that have been

made thus far, and are recorded in Executive Document No. 1, 47th Congress, second session, and Executive Document No. 5, 48th Congress, first session.

2°. A few tests made recently by David Kirkaldy.

While it is from these tests upon long joints that we can derive correct and reliable information to use in practice, and hence while the experiments already made give us some information in regard to such joints as were tested, nevertheless, as these tests have not yet been carried far enough to furnish all the information we need, and to settle cases that we are liable to be called upon to decide, therefore, before quoting the above experiments, some of the rules and proportions in use in practice at the present time, and the modes of determining them, will be first explained.

In this regard we must observe that practical considerations render it necessary to make the proportions different when the joint is in the shell of a steam-boiler, from the case when it is in a girder or other part of a structure.

In the case of boiler-work, the joint must be steam-tight, and hence the pitch of the rivets must be small enough to render it so: whereas in girder-work this requirement does not exist; and hence the pitch can, as far as this requirement goes, be made greater.

It is probable, that, with good workmanship, we might be able to secure a steam-tight joint with considerably greater pitches than those commonly used in boiler-work; and now and then some boiler-maker is bold enough to attempt it.

Tables of usual dimensions employed and recommended by Robert Wilson, Thomas Box, and Unwin respectively, will now be given.

The following tables give the proportions recommended by Robert Wilson for boiler-work, and by Thomas Box for girder-work:—

## PROPORTIONS GIVEN BY ROBERT WILSON FOR USE IN BOILER-WORK.

| Thickness of Plates. | Diameter of Rivets. All Lap-Joints and Butt-Joints with Single Strips. | Pitch of Rivets. Single-Riveted Lap-Joint. | Pitch of Rivets. Double-Riveted Lap-Joints, and Butt-Joints with Single Strips. | Double-Riveted Butt-Joints with Double Strips. |                  |
|----------------------|--|--|---|--|------------------|
|                      |  |  |   | Diameter of Rivet.                             | Pitch of Rivets. |
| $\frac{1}{8}$        | $\frac{1}{8}$  | $1\frac{1}{2}$                             | $1\frac{3}{4}$  | -  | -                |
| $\frac{1}{16}$       | $\frac{1}{8}$  | $1\frac{1}{2}$                             | $2\frac{1}{4}$  | -  | -                |
| $\frac{3}{16}$       | $\frac{1}{8}$  | $1\frac{3}{4}$                             | $2\frac{1}{2}$  | $\frac{1}{8}$                                  | $2\frac{1}{2}$   |
| $\frac{1}{4}$        | $\frac{3}{16}$   | $1\frac{7}{8}$                             | $2\frac{1}{2}$  | $\frac{1}{8}$                                  | $2\frac{3}{4}$   |
| $\frac{5}{16}$       | $\frac{3}{16}$   | $1\frac{7}{8}$                             | $2\frac{1}{2}$  | $\frac{1}{8}$                                  | $2\frac{3}{4}$   |
| $\frac{3}{8}$        | $\frac{1}{2}$  | $2\frac{1}{8}$                             | $2\frac{3}{4}$  | $\frac{1}{8}$                                  | $2\frac{7}{8}$   |
| $\frac{7}{16}$       | $\frac{1}{2}$  | $2\frac{1}{8}$                             | $2\frac{3}{4}$  | $\frac{1}{8}$                                  | 3                |
| $\frac{1}{2}$        | $\frac{1}{2}$  | $2\frac{1}{8}$                             | $2\frac{7}{8}$  | $\frac{1}{8}$                                  | $3\frac{1}{8}$   |
| $\frac{5}{8}$        | 1  | $2\frac{1}{4}$                             | $3\frac{1}{4}$  | $\frac{1}{8}$                                  | $3\frac{1}{4}$   |
| $\frac{3}{4}$        | 1  | $2\frac{1}{4}$                             | $3\frac{1}{4}$  | $\frac{1}{8}$                                  | $3\frac{1}{2}$   |
| $\frac{7}{8}$        | 1  | $2\frac{1}{2}$                             | $3\frac{1}{2}$  | 1  | $3\frac{5}{8}$   |
| 1                    | $1\frac{1}{8}$   | $2\frac{1}{2}$                             | $3\frac{1}{2}$  | 1  | $3\frac{3}{4}$   |
| 1                    | $1\frac{1}{8}$   | $2\frac{1}{2}$                             | $3\frac{1}{2}$  | $1\frac{1}{8}$                                 | 4                |

He gives, for the lap in single riveting, 3 times the diameter of the rivet, and never more than 3.3 times.

## PROPORTIONS RECOMMENDED BY THOMAS BOX FOR USE IN GIRDER-WORK.

## SINGLE-RIVETED LAP-JOINTS.

| Thickness of Plates. | Diameter of Rivets. | Pitch of Rivets. | Lap.           |
|----------------------|---------------------|------------------|----------------|
| $\frac{1}{8}$        | $\frac{1}{8}$       | $1\frac{1}{2}$   | 1              |
| $\frac{1}{16}$       | $\frac{1}{8}$       | $1\frac{1}{2}$   | $1\frac{1}{2}$ |
| $\frac{1}{4}$        | $\frac{1}{8}$       | $1\frac{1}{2}$   | $1\frac{3}{4}$ |
| $\frac{5}{16}$       | $\frac{3}{16}$      | $1\frac{3}{4}$   | $1\frac{1}{2}$ |
| $\frac{3}{8}$        | $\frac{3}{16}$      | 2                | $1\frac{1}{2}$ |
| $\frac{7}{16}$       | $\frac{3}{16}$      | $2\frac{1}{8}$   | $1\frac{7}{8}$ |
| $\frac{1}{2}$        | $\frac{1}{2}$       | $2\frac{1}{8}$   | 2              |

## DOUBLE-RIVETED JOINTS.

| Thickness of Plates. | Diameter of Rivets. | Pitch of Rivets. | Lap.           |
|----------------------|---------------------|------------------|----------------|
| $\frac{3}{8}$        | $\frac{1}{8}$       | $2\frac{1}{2}$   | $2\frac{1}{2}$ |
| $\frac{7}{16}$       | $\frac{3}{16}$      | 3                | 3              |
| $\frac{1}{2}$        | $\frac{3}{16}$      | $3\frac{1}{8}$   | $3\frac{1}{4}$ |
| $\frac{9}{16}$       | $\frac{1}{2}$       | $3\frac{1}{2}$   | $3\frac{3}{4}$ |
| $\frac{5}{8}$        | $\frac{1}{2}$       | $3\frac{3}{8}$   | $3\frac{3}{4}$ |
| $\frac{11}{16}$      | $1\frac{1}{8}$      | $3\frac{1}{2}$   | 4              |
| $\frac{3}{4}$        | $1\frac{1}{8}$      | $4\frac{1}{8}$   | $4\frac{1}{4}$ |

1°. In regard to the diameter of the rivets, Robert Wilson first shows, that by taking the crushing-strength in front of the rivet at 89600, and the shearing-strength of the rivet at 47040 lbs. per square inch, we should find that the joint would be safe against crushing the metal in front of the rivet with a diameter of rivet equal to  $2\frac{1}{2}$  times the thickness of the plate; he recommends the diameters given in the table, which for plates  $\frac{1}{4}$  inch and  $\frac{1}{8}$  inch thick are double the thickness of the plate (this being a rule frequently used), and for thicker plates they grow gradually less.

Thomas Box, in deducing his diameters for girder-work, gives the formula

$$d = \frac{3}{4}t + \frac{3}{16},$$

from which he calculates the diameters given in his table, giving this as an empirical rule.

2°. In regard to the pitch of the rivets, Robert Wilson, by calling the shearing-strength of the rivets per square inch equal to the tensile strength of the plate per square inch, deduces the formula

$$p = \frac{\pi d^2}{4t} + d.$$

The values recommended by him differ, however, somewhat from the results of this formula, in order to retain a larger section of plate between rivets.

Thomas Box deduces his values of the pitch by considering the shearing-strength of the rivet per square inch as equal to  $\frac{3}{4}$  the tensile strength of the plate per square inch, and then calculating the joint so as to give equal strength for tearing and shearing.

3°. In regard to the lap, Robert Wilson computes it so that there shall be strength enough to resist breaking through: his formula has been given in § 177. This would give, for the lap, the formula for single riveting,

$$l = 0.81d.$$

Hence he concludes that the common rule of making the distance between the hole and edge of the plate equal to the diameter of the rivet is to provide sufficient resistance in this regard: this rule, however, he contradicts by his empirical rule given just after the table.

Thomas Box, on the other hand, gives a graphical construction for the lap, which practically accounts the shearing and the tensile strength of the plate per square inch the same, and provides sufficient strength to prevent the rivet from shearing out the plate in front of it. His results are a little larger than three times the diameter of the rivet.

Next, as to Unwin's recommendations, —

1°. In regard to the diameter of rivet, he says that the diameters used in practice range from

$$d = \frac{3}{4}t + \frac{3}{8}$$

to

$$d = \frac{7}{8}t + \frac{3}{8},$$

and recommends, as a good rule to follow,

$$d = 1.2\sqrt{t}.$$

It will be seen that he is thus recommending a little larger diameters than Wilson or Box.

2°. As to the pitch, he determines it from the formula

$$(p - d)f_t = \frac{\pi}{4} d^2 f_s,$$

where  $p$  = pitch,  $t$  = thickness of plate,  $d$  = diameter of rivet,  $f_t$  = tensile strength of plate between rivet-holes after the riveting has been done,  $f_s$  = shearing-strength of rivet per square inch, using such values of  $f_t$  and  $f_s$  as he considers suitable. The result of all this will be shown in the following tables, given by Unwin.

*Ratio of Tearing and Shearing Strength  $\frac{f_t}{f_s}$  in Riveted Joints,  $f_t$  being Tensile Strength per Square Inch after the Plate has been Punched or Drilled.*

|                          | Iron Plates, Iron Rivets.                     |          | Steel Plates, Steel Rivets.                   |          |
|--------------------------|---|----------|---|----------|
|                          | Drilled or Punched, and Annealed or Rymerged. | Punched. | Drilled or Punched, and Annealed or Rymerged. | Punched. |
| Single-riveted . . . . . | 0.94  | 0.77     | 1.26  | 1.05     |
| Double-riveted . . . . . | 1.02  | 0.85     | 1.34  | 1.17     |
| Treble-riveted . . . . . | 1.05  | —        | 1.36  | —        |

*Values of Pitch for Single Riveting for Various Values of  $\frac{f_t}{f_s}$*

| Thickness of Plates.                    | Nominal Diameter of Rivets. | Real Diameter of Rivets. | Single Riveting.     |   |      |      |                       |   |      |      |
|---|-----------------------------|--------------------------|----------------------|---|------|------|-----------------------|---|------|------|
|   |                             |                          | Iron Rivets.         |   |      |      | Steel Rivets.         |   |      |      |
|   |                             |                          | Iron Punched Plates. | Iron Drilled or Punched, and Annealed or Rymerged Plates. |      |      | Steel Punched Plates. | Steel Punched and Annealed, or Rymerged Plates. |      |      |
|   |                             |                          |                      |   |      |      |                       |   |      |      |
|   |                             |                          |                      |   |      |      |                       |   |      |      |
| Pitch for values of $\frac{f_t}{f_s} =$ |                             |                          |                      |   |      |      |                       |   |      |      |
| 0.75                                    | 0.85                        | 0.95                     | 1.0                  | 1.05  | 1.15 | 1.25 | 1.35                  |   |      |      |
| $\frac{1}{8}$                           | $\frac{1}{16}$              | 0.72                     | 2.46                 | 2.25  | 2.09 | 2.02 | 1.96                  | 1.85  | 1.77 | 1.69 |
| $\frac{3}{16}$                          | $\frac{3}{16}$              | 0.78                     | 2.48                 | 2.28  | 2.12 | 2.06 | 1.99                  | 1.89  | 1.81 | 1.72 |
| $\frac{1}{4}$                           | $\frac{1}{8}$               | 0.85                     | 2.58                 | 2.38  | 2.22 | 2.15 | 2.09                  | 1.98  | 1.90 | 1.81 |
| $\frac{5}{16}$                          | $\frac{7}{16}$              | 0.92                     | 2.69                 | 2.48  | 2.32 | 2.25 | 2.19                  | 2.08  | 2.00 | 1.90 |
| $\frac{3}{8}$                           | $\frac{1}{2}$               | 0.98                     | 2.69                 | 2.40  | 2.25 | 2.19 | 2.13                  | 2.03  | 1.95 | 1.87 |
| $\frac{7}{16}$                          | $1\frac{1}{8}$              | 1.10                     | 2.79                 | 2.59  | 2.43 | 2.37 | 2.31                  | 2.20  | 2.12 | 2.04 |
| $\frac{1}{2}$                           | $1\frac{1}{4}$              | 1.17                     | 2.81                 | 2.62  | 2.46 | 2.40 | 2.34                  | 2.24  | 2.16 | 2.08 |
| 1                                       | $1\frac{1}{2}$              | 1.30                     | 3.07                 | 2.86  | 2.70 | 2.63 | 2.56                  | 2.45  | 2.36 | 2.28 |

By "real diameter" he means the diameter after riveting.

| Thickness of Plates. | Nominal Diameter of Rivets. | Real Diameter of Rivets. | Double Riveting.                              |   |      |                       |  |
|----------------------|-----------------------------|--------------------------|---|---|------|-----------------------|--|
|                      |                             |                          | Iron Rivets.                                  |   |      | Steel Rivets.         |  |
|                      |                             |                          | Iron Punched Plates.                          | Iron Drilled or Punched, and Ry-mered Plates. |      | Steel Punched Plates. | Steel Drilled or Punched, and Ry-mered Plates. |
|                      |                             |                          | Pitch of rivets for value $\frac{f_t}{f_s} =$ |   |      |                       |  |
|                      |                             |                          | 0.85  | 1.00  | 1.10 | 1.20                  | 1.35   |
| $\frac{1}{16}$       | $\frac{1}{8}$               | 0.72                     | 3.78  | 3.33  | 3.12 | 2.91                  | 2.66   |
| $\frac{3}{16}$       | $\frac{3}{8}$               | 0.78                     | 3.78  | 3.33  | 3.12 | 2.91                  | 2.66   |
| $\frac{1}{8}$        | $\frac{1}{2}$               | 0.85                     | 3.91  | 3.45  | 3.24 | 3.03                  | 2.77   |
| $\frac{3}{8}$        | $\frac{3}{4}$               | 0.92                     | 4.05  | 3.58  | 3.37 | 3.16                  | 2.88   |
| $\frac{1}{2}$        | $\frac{7}{8}$               | 0.98                     | 3.82  | 3.39  | 3.18 | 3.00                  | 2.76   |
| $\frac{3}{4}$        | $1\frac{1}{8}$              | 1.10                     | 4.08  | 3.63  | 3.42 | 3.22                  | 2.98   |
| $\frac{7}{8}$        | $1\frac{1}{4}$              | 1.17                     | 4.06  | 3.63  | 3.42 | 3.23                  | 2.99   |
| 1                    | $1\frac{1}{2}$              | 1.30                     | 4.42  | 3.95  | 3.74 | 3.52                  | 3.26   |

It will be noticed, that, having used a larger rivet than Wilson or Box, he naturally used a larger pitch.

For lap, he gives the following values, computed by the same rule as Wilson computes his, but with a different constant; and he then compares them with values of  $1.5d$ , which he states to be an ordinary rule.

| $d$              | $\frac{1}{4}$ | $\frac{1}{2}$ | $\frac{3}{4}$ | $1$  | $1\frac{1}{4}$ | $1\frac{1}{2}$ |
|------------------|---------------|---------------|---------------|------|----------------|----------------|
| For iron, $l =$  | 1.00          | 1.14          | 1.29          | 1.41 | 1.55           | 1.67           |
| For steel, $l =$ | 0.86          | 0.98          | 1.12          | 1.22 | 1.35           | 1.46           |
| $1.5d$           | 0.75          | 0.94          | 1.12          | 1.31 | 1.50           | 1.69           |

*Efficiency of the Joint.* — The efficiency of the joint is an item of great importance. Sir William Fairbairn's experiments gave the following efficiencies : —

|                                |               |
|--------------------------------|---------------|
| Entire plate . . . . .         | 100 per cent, |
| Double-riveted joint . . . . . | 76 “          |
| Single-riveted joint . . . . . | 56 “          |

and these efficiencies have been very much quoted and used.

Mr. Forney, in his “Catechism of the Locomotive,” gives the following : —

|   |       |
|---|-------|
| Solid plate . . . . .   | 100.0 |
| Single-riveted seam, punched holes, $\frac{1}{8}$ rivets . . . . .            | 50.5  |
| “ “ “ drilled “ $\frac{7}{8}$ “ . . . . .                                     | 60.0  |
| Double-riveted seam, drilled and zigzag holes, $\frac{3}{4}$ rivets . . . . . | 70.0  |
| “ “ “ “ “ “ $\frac{7}{8}$ “ . . . . .   | 72.0  |
| Single riveted seam, punched holes, with covering-plate . . . . .             | 65.3  |

On the other hand, Unwin gives the following tables for the efficiencies in different cases : —

| Thickness of Plates. | Nominal Diameter of Rivets. | Real Diameter of Rivets. | Single Riveting.                                       |      |   |      |                       |      |   |      |
|----------------------|-----------------------------|--------------------------|--|------|---|------|-----------------------|------|---|------|
|                      |                             |                          | Iron Punched Plates.                                   |      | Iron Drilled or Punched, and Annealed or Rymerged Plates. |      | Steel Punched Plates. |      | Steel Punched and Annealed, or Rymerged Plates. |      |
|                      |                             |                          | Efficiency of joints for values of $\frac{f_1}{f_2} =$ |      |   |      |                       |      |   |      |
|                      |                             |                          | 0.77   |      | 0.88  |      | 0.9                   |      | 1.0   |      |
| $\frac{1}{8}$        | $\frac{1}{8}$               | 0.72                     | 0.55   | 0.52 | 0.58  | 0.56 | 0.57                  | 0.55 | 0.59  | 0.57 |
| $\frac{3}{16}$       | $\frac{3}{16}$              | 0.78                     | 0.53   | 0.51 | 0.55  | 0.54 | 0.55                  | 0.53 | 0.57  | 0.55 |

*Punching and Drilling.* — One matter in this connection that has occupied a good deal of attention is the relative advantages of punched and drilled holes. The usual practice is to punch the holes, and it is less expensive than drilling them.

On the other hand, it is generally acknowledged, and has been shown by a number of experimenters, that punching in most cases injures the metal around the hole: the amount of this injury may vary from a very small quantity up to 20 per cent in iron, and up to 35 per cent in steel, plates. The amount of injury will vary according to the quality of the plate, and also according to the amount of clearance between the punch and the die; the injury being less in plates of good quality and ductile, and greater in hard and brittle plates, also less when the clearance between the punch and the die is ample than when it is too small.

Accounts of tests on this subject are to be found in —

Sir William Fairbairn : Application of Iron to Building Purposes.

J. Barba : Use of Steel in Construction.

A. F. Hill : Paper in the Proceedings of Society of Engineers of Western Pennsylvania.

Executive Document No. 1, 47th Congress, 2d session, p. 142 *et seq.*

Executive Document No. 5, 48th Congress, 1st session.

There are two other matters that sometimes appear to modify these statements as far as breaking-strength is concerned ; i.e., —

1°. When the specimen is a grooved one, as it must be when punched or drilled, its apparent ultimate strength in the testing-machine is greater than it would be if it had any opportunity to stretch.

2°. Cold-punching has, to a small extent, a similar effect to cold-rolling ; i.e., it may harden the metal a little, and increase its breaking-strength on this account, while rendering it less ductile, and hence more brittle.

The injury done by punching may be almost entirely removed in either of the following ways :—

1°. By annealing the plate.

2°. By reaming out the injured portion of the metal around the hole ; i.e., by punching the hole a little smaller than is desired, and then reaming it out to the required size. This removing the injurious effect of punching is more needed in steel than in iron plates.

There is a certain friction developed by the contraction of the rivets in cooling, tending to resist the giving-way of the joint ; but this is likely to disappear before fracture takes place, and cannot, therefore, be depended upon.

The shearing-strength of the rivets would appear to be about  $\frac{3}{4}$  or  $\frac{2}{3}$  the tensile strength of the plate.

*Government Experiments.* — These experiments form, as has been already stated, the first portion of a systematic series; and the tables of results are given here, because it seems to the author, that, although the series is not yet completed, yet these tests themselves furnish more reliable information in regard to the behavior and the strength of joints made somewhat in these proportions than any other experiments that have been made, and that the figures themselves furnish the engineer with the means of using his judgment in many cases where he had no reliable data before.

Thus it is plain, that, when we compute the crushing-strength in front of the rivet, it is not this direct crushing action that is produced, as the small piece of plate that lies in front of a rivet would not bear so much unless re-enforced by the metal on the sides.

Nevertheless, the compression per square inch on the bearing-surface of the rivet (i.e., the pull on one rivet divided by the longitudinal projection of its bearing on one plate, however it be resisted) apparently forms an important element in the strength of the joint, and shows the advantage of large rivets; this being one of the deductions made by Mr. James E. Howard (who conducted the tests) from these tests, inasmuch as some of the experiments tried with the same section of plate between the holes, and with rivets of different size, showed a greater efficiency for the larger rivets.

In calculating the resistance to tearing out of the plate in front of the rivet by the rules of Wilson or Unwin, we must observe that there is not the action that is considered in the formulæ.

The forces brought into play are more complex, and it is only experiment that can show us what they are.

A perusal of the tables will give a good idea of the shearing-strength per square inch of the rivet iron, which is seen to be less than the tensile strength of the solid plate; also the

loss of strength of the plates due to the entire process of riveting, punching, drilling, and driving the rivets; also the efficiencies of the joints tested.

One of the strongest single-riveted joints tested was a single-riveted lap-joint with a single covering-strip.

The apparent anomaly of the punched plates in a few cases, showing a greater strength than the drilled plates, is explained by Mr. Howard to be due to the strengthening effect of cold-punching combined with smallness of pitch, inasmuch as then the masses of hardened metal on the two sides re-enforce each other.

Further than this, the student is left to study the figures themselves as to the effect of different proportions, etc.

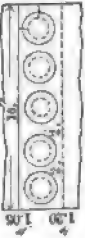

In regard to these tests, it is stated in the report that —

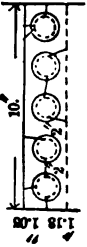

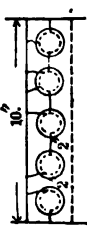

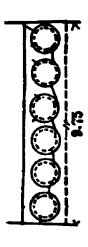

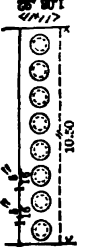

1°. "The wrought-iron plate was furnished by one maker out of one quality of stock."

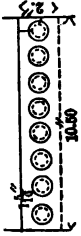

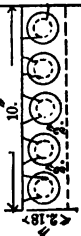

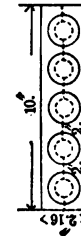

2°. "The steel plates were supplied from one heat, cast in ingots of the same size; the thin plates differing from the thicker plates only in the amount of reduction given by the rolls."

The modulus of elasticity of the metal was, iron plate, 31970000 lbs.; steel plate, 28570000 lbs.

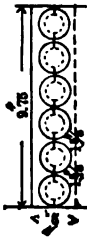

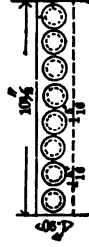

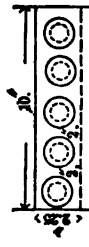

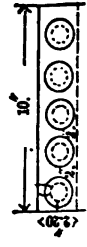

In the tabulated results, the manner of fracture is shown by sketches of the joints, and is further indicated by heavy figures in columns headed "Maximum Strains on Joints, in lbs., per Square Inch."

The following tests, made recently by David Kirkaldy, are also quoted from Executive Document No. 48, 47th Congress, second session, p. 24 *et seq.*

These tests were made on joints of  $\frac{7}{8}$ -inch steel plate. The rivet-holes of 1418, "4," 1406, "1," 1410, "2," and 1414, "3," were drilled separately with a  $1\frac{1}{8}$ -inch drill. The plates were then heated, as the boiler-plates themselves would be for rolling, and, after cooling, were put together, and the holes reamed out to  $1\frac{1}{8}$  inch.

The rivet-holes of the remainder were punched separately with a  $\frac{7}{8}$ -inch punch on a  $1\frac{1}{8}$ -inch die. The plates were then treated like the others. All samples were riveted together the full width of the plates, 24 inches.

The efficiencies deduced from the Watertown experiments are not summed up here, as they can be obtained from the tables.

On page 480 will be given the tests of grooved specimens of wrought-iron and steel made at the arsenal on plates used in the joints already referred to. These plates include both punched and drilled plates, and vary in thickness from  $\frac{1}{4}$  inch to 1 inch.

§ 233. **Chain Cable.**—The most thorough set of tests of the strength of chain cable is that made by Commander Beardslee for the United-States government, an account of which may be found either in the report already referred to, or in the abridgment by William Kent.

In this report are to be found a number of conclusions, some of which are as follows:—

1°. That cables made of studded links (i.e., links with a cast-iron stud, to keep the sides apart) are weaker than open-link cables.

2°. That the welding of the links is a source of weakness; the amount of loss of strength from this cause being a very uncertain quantity, depending partly on the suitability of the iron for welding, and partly on the skill of the chain-welder.

3°. That an iron which has a high tensile strength does not necessarily make a good iron for cables. Of the irons tested, those that made the strongest cables were irons with about 51000 lbs. tensile strength.

4°. The greatest strength possible to realize in a cable per square inch of the bar from which it is made being 200 per cent of that of the bar-iron from which it was made, the cables tested varied from 155 to 185 per cent of that of the bar-iron.

5°. The Admiralty rule for proving chain cables, by which they are subjected to a load in excess of their elastic limit, is objected to, as liable to injure the cable: and the report suggests, in its place, a lower set of proving-strengths, as given in the following table; the Admiralty proving-strengths being also given in the table.

In these recommendations, account is taken of the different proportion of strength of different size bars as they come from the rolls, also no proving-stress is recommended greater than 50 per cent of the strength of the weakest link, and 45.5 per cent of the strongest; whereas in the Admiralty tests, 66.2

per cent of the strength of the weakest, and 60.3 per cent of the strongest, is sometimes used.

For the details of this investigation, see the report, Executive Document No. 98, 45th Congress, second session, or the abridgment already referred to.

§ 234. **Iron and Steel Wire.**—It has long been known that the process of cold-drawing, by which wrought-iron and steel are made into wire, greatly increases its strength per square inch; and usually the smaller the wire, the greater the strength per square inch. Thus iron wire varies in strength from about 70000 to about 90000 lbs. per square inch when unannealed, its strength being reduced to 45000 or 50000 lbs. by being annealed.

In steel wire unannealed, the strength runs up even to 200000 lbs. per square inch in some cases; and Fairbairn even records strengths as great as 275000 lbs. per square inch.

Accounts of experiments upon the strength and elasticity of wrought-iron and steel wire will be found in —

W. E. Woodbridge : Report on the Mechanical Properties of Steel.

Professor Thurston : Materials of Engineering and other papers.

Pocket-Book of the New-Jersey Iron and Steel Company.

The strength of wire becomes of special importance in connection with wire rope, and also with wire-wound guns. Dr. Woodbridge has made a great number of tests of steel wire for wire-wound guns.

*Wire Rope.* — Inasmuch as wire rope is extensively used in the transmission of power, it may be a matter of convenience to have here a table giving the strength of the rope as claimed by some of the makers. There will follow, therefore, the table of strengths of the different sizes as given by Mr. John A. Roebling for the rope manufactured by him, and also some of his remarks in regard to its use : —

*Rope of 133 Wires, or 19 Wires to the Strand.*

| Trade Number.    | Circumference, in inches. | Ultimate Strength, in lbs. | Circumference of Hemp Rope of the Same Strength. |

*Notes by Mr. Roebling.* — "Two kinds of wire rope are manufactured. The most pliable variety contains nineteen wires in the strand, and is generally used for hoisting and running rope. The ropes with twelve wires and seven wires in the strand are stiffer, and are better adapted for standing-rope, guys, and rigging. Ropes are made up to three inches in diameter, both of iron and steel, upon special application.

"For safe working-load, allow one-fifth to one-seventh of the ultimate strength, according to speed, so as to get good wear from the rope. When substituting wire rope for hemp rope, it is good economy to allow for the former the same weight per foot which experience has approved for the latter.

"Wire rope is as pliable as new hemp rope of the same strength: the former will therefore run over the same size sheaves and pulleys as the latter. But the greater the diameter of the sheaves, pulleys, or drums; the longer wire rope will last. In the construction of machinery for wire rope, it will be found good economy to make the drums and sheaves as large as possible.

"Experience has demonstrated that the wear increases with the speed. It is therefore better to increase the load than the speed.

"Wire rope is manufactured either with a wire or a hemp centre. The latter is more pliable than the former, and will wear better where there is short bending.

*"Wire rope must not be coiled or uncoiled like hemp rope.* When mounted on a reel, the latter should be mounted on a spindle or flat turn-table, to pay off the rope. When forwarded in a small coil without reel, roll it over the ground like a wheel, and run off the rope in that way. All untwisting or kinking must be avoided."

In the case of wire rope it is true, as in all other cases, the only way to secure certainty in regard to the strength is to test it. The author has tested wire rope which bore no more than

two-thirds the strength claimed for it; though it is but justice to say, in this connection, that the few samples of Roebling rope tested in his laboratory bore out very fairly the results given for the sizes tested in the table.

A number of tests of wire rope have been made on the government testing-machine at Watertown Arsenal and elsewhere.

Wire rope is generally used with some kind of holder, and it is generally the case that the breakage of the rope occurs at the holder.

Another matter worth noticing is, that it yields in detail, and hence that new rope is not as strong as that which has been under tension for some time, provided the tension has not been excessive,

§ 235. **Other Metals and Alloys.**—Copper is, next to iron and steel, the metal most used in construction, sometimes in the pure state, especially in the form of sheets or wire, but more frequently alloyed with tin or zinc; those metals where the tin predominates over the zinc being called bronze, and those where zinc predominates over tin, brass. Copper in the pure state was used not long ago for the fire-box plates of locomotive and other steam-boilers, as it was believed to stand better the great strains due to the changes of temperature that come upon these plates, than iron or steel; but now steel or iron has almost entirely superseded it for this purpose, except in some cases where the feed-water is very impure, and where the impurities are such as corrode iron.

The alloys of copper, tin, and zinc which are used most where strength and toughness are needed, are those where the tin predominates over the zinc; and the composition, mode of manufacture, and resisting properties of these metals, together with the effect of other ingredients, as phosphorus, have been very extensively investigated with reference to their use as a material for making guns, instead of cast-iron.

Accounts of tests made on these alloys will be found as follows:—

Major Wade: Ordnance Report, 1856.

T. J. Rodman: Experiments on Metals for Cannon.

Executive Document No. 23, 46th Congress, 2d session.

No attempt will be made to give a complete account of the results of these tests; but a table will be given for convenience of use, showing rough average values of the resisting powers of some metals and alloys other than iron.

|  | Specific Gravity. | Tensile Strength per Sq. In. | Modulus of Elasticity. |
|--|-------------------|------------------------------|------------------------|
| Brass cast . . . . .                   | 8.396             | 18000                        | 9170000                |

| 34.92 " + 65.08 " (small bells) .      | 8.056             | 3136                         | —                      |
| 15.17 " + 84.83 " (speculum metal)     | 7.447             | 6944                         | —                      |
| Tin . . . . .                          | 7.291             | 5600                         | —                      |
| Zinc . . . . .                         | 6.861             | 7500                         | —                      |
| Copper cast . . . . .                  | 8.712             | 24138                        | —                      |
| Copper bolts . . . . .                 | 8.878             | 33000                        | —                      |
| Copper wire . . . . .                  | —                 | 60000                        | 17000000               |
| Gold cast . . . . .                    | 19.258            | 20000                        | —                      |
| Silver cast . . . . .                  | 10.476            | 40000                        | —                      |
| Platinum wire . . . . .                | 22.069            | 56000                        | —                      |
| Lead cast . . . . .                    | 11.352            | 1800                         | —                      |

Professor Thurston gives, for the ultimate tensile strength per square inch of a compound of copper and tin and zinc,

$$T = 30000 + 1000t + 500z,$$

where  $t$  = percentage of tin, and not over 15 per cent; and  $z$  = percentage of zinc, and not over 50 per cent.

Some specimens of phosphor bronze tested by Kirkaldy gave for tensile strengths from 22000 to 50000 for cast, and 98000 to 159000 for phosphor bronze wire 0.06 inch to 0.11 inch diameter. If the student is to use alloys, he should ascertain their strength, elastic limit, and modulus of elasticity, and he should observe that the mode of manufacture has a great influence on the strength and ductility of any alloy.

§ 236. **Timber.** — However extensively iron and steel may have superseded timber in construction, nevertheless, there are many cases in which iron is entirely unsuitable, and where timber is the only material that will answer the purpose; and in many cases where either can be used, timber is much the cheaper. Hence it follows that the use of timber in construction is even now, and as it seems always will be, a very important item.

Another advantage possessed by timber is, that, on yielding, it gives more warning than iron, thus affording an opportunity to foresee and to prevent accident.

If we make a section across any of the exogenous trees, as the oak, pine, etc., we shall find a series of concentric layers; these layers being called annual rings, because one is generally deposited every year.

Radiating from the heart outwards will be found a series of radial layers, these being known as the medullary rays.

Of the annual rings, the outer ones are softer and lighter in color than the inner ones; the former forming the sap-wood, and the latter the heart-wood. When the log dries, and thus tends to contract, it will be found that scarcely any contraction takes place in the medullary rays; but it must take place along the line of least resistance, viz., along the annual rings, thus causing radiating cracks, and drawing the rays nearer together on the side away from the crack. This action is exhibited in

Fig. 241, where a log is shown with two saw-cuts at right angles to each other; when this log becomes dry, the four right angles all becoming acute through the shrinkage of the rings.

If the log be cut into planks by parallel saw-cuts, the planks will, after drying, assume the forms shown in Fig. 242, as is pointed out in Anderson's "Strength of Materials," from which these two cuts are taken.

FIG. 241.

FIG. 242.

This internal construction of a plank has an important influence upon the side which should be uppermost when it is used for flooring; for, if the heart side is uppermost, there will be a liability to having layers peel off as the wood dries: indeed, boards for flooring should be so cut as to have the annual rings at right angles to the side of the plank. Before discussing any other considerations which affect the adaptability of timber to use in construction, we will consider the question of its strength.

**§ 237. Strength of Timber.**—In this regard we must observe, that, whereas the strength and elasticity and other properties of iron and steel vary greatly with its chemical composition and the treatment it has received during its manufacture, the strength, etc., of timber is much more variable, being seriously affected by the soil, climate, and other accidents of its growth, its seasoning, and other circumstances; and that over many of these things we have no control: hence we must not

expect to find that all timber that goes by one name has the same strength, and we shall find a much greater variation and irregularity in timber than in iron. The experiments that have been made on strength and elasticity of timber may be divided into the following classes:—

1°. Those of the older experimenters, except those made on full-size columns by P. S. Girard, and published in 1798. A fair representation of the results obtained by them, all of which were deduced from experiments on small pieces, is to be found in the tables given in Professor Rankine's books, "Applied Mechanics," "Civil Engineering," and "Machinery and Millwork."

2°. Tests made by modern experimenters on small pieces. Such tests have been made by —

- (a) Trautwine: *Engineers' Pocket-Book*.
- (b) Hatfield: *Transverse Strains*.
- (c) Laslett: *Timber and Timber Trees*.
- (d) Thurston: *Materials of Construction*.
- (e) A series of tests on small samples of a great variety of American woods, made for the Census Department, and recorded in Executive Document No. 5, 48th Congress, 1st session.

3°. Tests made by Capt. T. J. Rodman, U.S.A., the results of which are given in the "Ordnance Manual."

4°. All tests that have been made on full-size pieces.

In regard to tests on small pieces, such as have commonly been used for testing, it is to be observed, that, while a great deal of interesting information may be derived from such tests as to some of the properties of the timber tested, nevertheless, such specimens do not furnish us with results which it is safe to use in practical cases where full-size pieces are used. Inasmuch as these small pieces are necessarily much more perfect (otherwise they would not be considered fit for testing), having less defects, such as knots, shakes, etc., than the full-size pieces,

they have also a far greater homogeneity. They also season much more quickly and uniformly than full-size pieces. In making this statement, I am only urging the importance of adopting in this experimental work the same principle that the physicist recognizes in all his work; viz., that he must not apply the results to cases where the conditions are essentially different from those he has tested.

Moreover, it will be seen in what follows, that, whenever full-size pieces have been tested, they have fallen far short of the strength that has been attributed to them when the basis in computing their strength has been tests on small pieces; and, moreover, the irregularities do not bear the same proportion in all cases, but need to be taken account of.

The results of the first class of experiments named in the following table are taken from Rankine's "Applied Mechanics;" and, inasmuch as the table contains also the strengths of some other organic fibres, it will be inserted in full. The student may compare these constants with those that will be given later.

In regard to the tests of the second class, a few comments are in order:—

1°. These experiments, like those of the first class, were all made upon small pieces; and the results are correspondingly high.

The usual size of the specimens for crushing being one or two square inches in section, and of those for transverse strength being about two inches square in section and four or five feet span, those for tension had even a much smaller section than those for compression; as it is necessary, in order to hold the wood in the machine, to give it very large shoulders.

The only exception to this is the tests of Sir Thomas Lasset, an account of which is given in his "Timber and Timber Trees," and also in D. K. Clark's "Rules and Tables." In these tests he gives very much lower tensile strengths than those given above; and he states that his specimens were three inches square, but does not say how he managed to hold them in such a way as to subject them to a direct tensile stress. His results for crushing and transverse strength are about as great as

those given in Rankine's tables, and as were obtained by the other experimenters on small pieces, as his specimens were of about the same dimensions as those used by the others. The figures obtained by these experimenters will only be given incidentally, as —

(a) They are very similar to those given in Rankine's table.  
(b) They are not suitable for practical use on the large scale.

(c) While they have been used, it has only been done by employing a very large factor of safety for timber.

The series of tests made for the Census Department, and recorded in Executive Document No. 5, 48th Congress, first session, form a very interesting series of experiments upon small specimens of an exceedingly large number of American woods. In order to have working figures, we should need to test large pieces of the same; as the proportion between the strengths of the different kinds would be liable to be different in the latter case.

We will next consider Rodman's experiments. The only record of them available is a table of results in the "Ordnance Manual," and this table is appended here. It will be seen, on comparing it with the former table, that the results are lower as a rule than those obtained by the experimenters of the first or second class. This is to be accounted for by the fact, that, while he did not experiment on full-size pieces, he used much larger pieces than those heretofore employed; his specimens for transverse strength, many of which are still stored at the Watertown Arsenal, being  $5\frac{3}{4}$  inches deep,  $2\frac{7}{8}$  inches thick, and 5 feet span.

In the table, the modulus of rupture will be given, instead of one-sixth of its value, which is the constant given in the "Ordnance Manual."

The fourth class of tests are those which furnish reliable data for use in construction ; and we will proceed to a consideration of these, taking up (1°) tension, (2°) compression, (3°) transverse strength, and (4°) shearing along the grain.

## TENSION.

In all cases where the attempt has been made to experiment upon the tensile strength of timber, a great deal of difficulty has been encountered in regard to the manner of holding the specimens. In all cases it has been found necessary to provide them with shoulders, each shoulder being five or six times as long as the part of the specimen to be tested, and to bring upon these shoulders a powerful lateral pressure, to prevent the specimen from giving way by shearing along the grain, and pulling out from the shoulder, instead of tearing apart.

The specimens tested have generally had a sectional area less than one square inch, and it seems almost impossible to provide the means of holding larger specimens. This being the case, it is plain, that, whenever timber is used as a tie-bar in construction (except in exceedingly rare and out-of-the-way cases), it will give way by some means other than direct

tension ; i.e., either by the pulling-out of the bolts or fastenings, and the consequent shearing of the timber, or else by bending if there is a transverse stress upon the piece ; and, this being the case, these other resistances should be computed, instead of the direct tension. Hence, while the direct tensile strength of timber may be an interesting subject of experiment, it can serve hardly any purpose in construction ; and the conclusion follows, that the resistances of timber to breaking we may expect to meet in practice are its crushing, transverse, and shearing strength. Indeed, the use of timber for a tie-bar should be avoided whenever it is possible to do so ; and, when it is used, the calculations for its strength should be based upon the pulling-out of the fastenings, the shearing or splitting of the wood, etc., and not on the tensile resistance of the solid piece.

Moreover, when a wooden tie-bar is loaded, in addition, with a transverse load, and when the magnitude of this transverse load is so great as to render the piece more liable to give way by cross-breaking than by the pulling-out of the fastenings, we must then compute the greatest tension per square inch at the outside fibre due to the bending, and to that add the direct tension per square inch : and this sum must be less than the modulus of rupture if the piece is not to give way ; i.e., the modulus of rupture, and not the ultimate tensile strength per square inch, must be our criterion of breaking in such a case, the working-strength per square inch being the modulus of rupture divided by a suitable factor of safety.

#### COMPRESSIVE STRENGTH.

- Tests of the compressive strength of full-size wooden columns are, with the exception of one set of tests, of very recent date, and have not yet found their way, to any extent, into our text-books and engineers' handbooks. It is therefore only

suitable, that, before enumerating them, we should observe what formulæ have been given in these books for the computation of timber columns in practice, what experimental basis these formulæ rest upon, and how they coincide with the facts.

The oldest formulæ are those of Euler. His formulæ for the strength of such circular columns as yield by bending are as follows:—

For ends fixed in direction,

$$P = \frac{(3.1416)^3}{16} E \frac{d^4}{l^3},$$

For rounded ends,

$$P = \frac{(3.1416)^3}{64} E \frac{d^4}{l^3};$$

where  $P$  = breaking-weight in pounds, and  $E$  = modulus of elasticity of the material. For wood, Weisbach gives for use in Euler's formulæ,  $E = 1664000$ , and crushing-strength per square inch = 6770.

According to Hodgkinson, we should take one-ninth of the breaking-strength of a cast-iron pillar, as given by equations (1), (2), (3), (4), (5), § 211; this being the rule given by Mr. James B. Francis in his book, where he has computed and tabulated the strength of pillars of the ordinary sizes used in practice, by means of Mr. Hodgkinson's formulæ.

In Gordon's formula the constants used were determined in such a way as to make the results agree as nearly as possible with Hodgkinson's experiments. The formulæ devised by Gordon himself refer only to cylindrical and hollow cylindrical columns. A formula devised by the same course of reasoning, and also depending for its constants on Hodgkinson's experiments, but so arranged as to be applicable to any form of

section whatever, is given by Professor Rankine. For wood it is as follows :

$$P = \frac{7200S}{1 + \frac{l^2}{3000r^2}},$$

where  $P$  = breaking-strength in pounds,  $S$  = sectional area in square inches,  $l$  = length in inches,  $r$  = least radius of gyration in inches.

Besides the above, we have formulæ which are practically Rankine's formulæ with the constants changed. One of these is that of Mr. C. Shaler Smith as given in Trautwine's "Pocket-Book," and applicable, as he claims, to a square or rectangular column of white or yellow pine. It is as follows :

$$P = \frac{5000S}{1 + 0.004 \frac{l^2}{d^2}},$$

where  $P$  = breaking-weight in pounds,  $S$  = sectional area in square inches,  $l$  = length in inches,  $d$  = least side of rectangle.

I have computed, by means of these formulæ, the breaking-weights of certain oak columns, with the following results :—

Length = 14 feet.

|                 |                        | Diameter<br>10.5 Inches. | Diameter<br>9.5 Inches. |
|-----------------|------------------------|--------------------------|-------------------------|
| Euler . . . .   | { Flat ends . . . . .  | 586214                   | 479858                  |
|                 | { Rounded ends . . . . | 347147                   | 232623                  |
| Rankine . . . . | { Flat ends . . . . .  | 465261                   | 360164                  |
|                 | { Rounded ends . . . . | 263615                   | 191286                  |
| Francis . . . . | { Flat ends . . . . .  | 420000                   | 312795                  |
|                 | { Rounded ends . . . . | 140000                   | 104265                  |

If we use the average of the results obtained from the oak columns tested at Watertown, which will be referred to later, we should find, for the breaking-weights of the above columns with flat ends, about 277000 and 227000 lbs. respectively.

A glance at the above results will show that they differ very much from each other, and the question naturally arises as to the trustworthiness of the experimental data on which they are based.

The constants used in Euler's formulæ are not deduced from any experiment on the breaking of a column.

Rankine's and Francis's have, for experimental basis, the experiments of Hodgkinson. He made a very large number of tests of cast-iron columns, none of which were as large as those used in practice. On oak columns, he made seventeen experiments on as many columns, all cut from one good plank of Dantzic oak, the largest of which was five feet long and two inches square. Of these seventeen, only seven were used in deducing his formulæ.

It is plain that such data are insufficient, and cannot furnish us reliable information as to the strength of a column.

As to Mr. C. Shaler Smith's formula, it is based upon some experiments made by himself, which have never been published. The student can easily satisfy himself as to how accurately it represents the facts on the large scale, by computing by it the strength of some of the columns tested, of which an account will shortly be given. Trautwine, in his "Handbook," states that it is "for the breaking-loads of either square or rectangular pillars or posts, of moderately seasoned white and common yellow pine, with flat ends, firmly fixed, and equally loaded."

Mr. Smith, as I understand, however, intended it to meet the case of such ill-fitting joints as occur in practice, and not for perfectly even bearings.

## TESTS OF FULL-SIZE COLUMNS.

The only tests of full-size columns of which I have any knowledge are :—

1°. Trautwine, in his "Handbook," speaks of some tests of wooden pillars 20 feet long and 13 inches square, made by David Kirkaldy, which, as he says, gave results agreeing with Mr. C. Shaler Smith's rule.

2°. A series of tests made at the Watertown Arsenal for the Boston Manufacturers' Mutual Fire Insurance Company, under the direction of the author.

3°. The tests that have been made at the Watertown Arsenal on the government testing-machine.

4°. Besides these, the writer has very recently had his attention called to a series of tests of full-size columns of oak and fir, made by P. S. Girard in 1798, which give results agreeing very well with the modern results on full-size columns. Why these tests should have been lost sight of, and Hodgkinson's always used instead, is incomprehensible.

In regard to the first, no details or results are given : hence nothing will be said about them.

In regard to the second, a summary only will be presented here, the reader being referred for details to my published report entitled "Strength of Wooden Columns."

## TESTS OF YELLOW-PINE POSTS AND BLOCKS.

1st set.

2d set.

2d set.

**TESTS OF OLD AND SEASONED WHITE-OAK POSTS.**

[illegible]

In all the experiments enumerated in the tables given above, the columns gave way by direct crushing, and hence the strength of columns of these ratios of length to diameter can properly be found by multiplying the crushing-strength per square inch of the wood by the area of the section in square inches.

This conclusion is deduced from the fact that the deflections were measured in every case, and found to be so small as not to exert any appreciable effect.

In regard to other tests of this same set, there were eight tests made, in addition to those already enumerated; and of these, five were loaded off centre. A summary of the results is appended, together with a comparison of their actual strength with that which would be computed on the basis of 4400 per square inch for yellow pine, and 3000 for oak.

| 3, 2d series | 236                | 11                                | 11.2  | 8.2                       | 1.55                      | 50.92                                      | 1.91                                | 100000                | 152760                            |

These results exhibit a great falling-off of strength due to the eccentricity of the load; and if we observe, that, whenever the beam on one side of a column is loaded differently from that on the other side, we have an eccentric loading, and hence

a falling-off in strength, we must conclude that this should be taken into account. Probably the best way to proceed in the matter is to compute always the greatest eccentricity possible in any given case, and to compute from that the additional stress on the column due to the bending consequent on this eccentricity by the principles of the short strut, already explained in § 207. This will always be on the safe side. The three remaining experiments of the set were, (1°) Two tests of whitewood columns: these gave a crushing-strength of 3009 lbs. per square inch. The columns were, however, brittle, and did not give warning of fracture. (2°) One yellow-pine square column of a sectional area of 68.8 square inches, and length 12 feet 6.85 inches, tested by resting one end on a thick yellow-pine bolster, crushing this bolster at right angles to the grain.

Maximum load on the post while the bolster was in, was 120000 lbs. = 1744 lbs. per square inch. Under this load a crack at end of post was enlarged, giving evidence that failure of the post was imminent. The bolster in the mean time had become thoroughly cracked, owing to the unequal distribution of the load on the bolster, from imperfect workmanship. Slight cracks followed the first snapping sounds heard at 20000 lbs. compression. The cracks gradually developed as the loads were increased, the side nearest the heart of the bolster sliding off.

The post was taken from machine and bolster removed. The post was cut off  $1\frac{1}{2}$  inches at the end, and squared; the total length, after cutting, being 149.35 inches. Ultimate strength, 375000 lbs. = 5451 lbs. per square inch.

A few of the conclusions in regard to these sizes of posts will now be quoted from the report of these tests, in which some general recommendations are made, and others having special reference to mill columns:—

1. I should recommend that the longitudinal holes in wooden mill columns be bored from one end only, and that all posts be rejected in

which the eccentricity at the other end is greater than a given small amount, as three-quarters of an inch. This recommendation is made in view of the facts that holes bored from the two ends are very liable not to meet in the middle, and hence not to allow a circulation of air; that, if the hole becomes very eccentric, the column is liable to be weakened; and also by the presence of two holes at the same section.

2. I should recommend that mill columns be not tapered, as the tapering is a source of weakness; the loss of strength in one of the cases tested amounting to about 120000 lbs.

3. I should also recommend that square columns be used in mills, instead of round ones, for the reason that the timber comes to the wharf in the form of square logs, and, when the columns are made round, they are cut from the square form; and this cutting-away of the wood is so much loss of strength.

4. The strength of a column of hard pine or oak, with "flat ends," the load being uniformly distributed over the ends, and of the diameters tested, is practically independent of the length up to a length of twelve feet (how much farther can only be decided by further experiment), such columns giving way practically by direct crushing; the deflection, if any, being as a rule very small, and exerting no appreciable influence on the breaking-strength.

5. The only exceptions to the above are found in cases where there is good reason for departure from the rule, as in the case of very imperfect wood or of very eccentric holes; but even there the influence of the deflection in reducing the strength is not nearly so great as has been generally supposed.

6. No formulæ founded on the generally received hypothesis, that the deflection exerts a very considerable influence on the breaking-strength of such columns as those referred to, represent correctly their breaking-strength for all lengths and diameters.

7. For such columns as those referred to, the most correct rule for determining the breaking-strength is to multiply the number of square inches in the section (the smaller section being used in the case of tapering columns) by the crushing-strength per square inch of the wood.

8. The crushing-strength per square inch varies considerably in

specimens of different degrees of seasoning, also in large and small specimens.

9. The average crushing-strength of wood is much less than has been supposed by many. That of some very highly seasoned hard pine was found at the arsenal to be 7386 lbs. For some hard pine of very slow growth and very highly seasoned, an average crushing-strength was found of 9339 lbs. For some very wet and green, they found a crushing-strength of 3015 lbs. For some yellow pine which had been seasoning about three months, I found 5400 lbs. For average crushing-strength of such posts as I tested, not thoroughly seasoned, and not very green, I found about 4400 lbs.; whereas in none of these cases did I obtain a greater result than about 4700 lbs. Hence it would be entirely unfair to assume a crushing-strength of 8000 lbs. for yellow pine. For two specimens of white oak tried at the arsenal, and very thoroughly seasoned, an average was obtained of about 7150 lbs.; whereas for such oak as was furnished me, which was green and knotty, but no more so than is usual for use in building, I obtained an average of about 3200 lbs.

10. I would recommend the use of iron caps and pintles, instead of wooden bolsters, as wood is very weak to resist crushing across the grain, and the wooden bolster will fail at a pressure far below that which the column is capable of resisting; and the unevenness of the pressure brought about by the bolster is so great as to sometimes crack the column at a pressure far below what it would otherwise sustain.

11. Any cause which operates to distribute the pressure on the ends unevenly, or to force its resultant out of centre, is a source of weakness, and brings about a very considerable deflection, which exerts an important influence in reducing the breaking-strength.

12. As far as these experiments have gone, it appears that such pintles as were used in these tests, when the fitting is perfect, exert no influence upon the breaking-strength of perfect and straight-grained columns, but that they probably are a source of weakness in the case of imperfect and knotty wood, and especially in cases where there is an incipient deflection. Further experiment is needed, however, to answer these questions fully.

13. I would also recommend that the horizontal holes connecting

the longitudinal holes with the outside air, be made in the iron cap, and not in the wood: this will prevent weakening of the post by the hole, and will prevent the closing of the hole by change in moisture and other causes.

14. Another conclusion which I think is very evident, is, that the crushing-strength of full-size columns cannot be fairly inferred from tests made on columns no larger than five feet long and two inches on a side.

The table of results of the tests on old and seasoned oak columns were made upon columns that had been in use for a number of years in different mills, from which they were removed, and replaced by new ones. Ten of them had been in use about twenty-five years, and the remainder for shorter periods. An inspection of this table will, I think, convince the reader that it would not be safe to calculate upon a higher breaking-strength per square inch in these than in the green ones.

#### TESTS MADE ON THE GOVERNMENT MACHINE.

In Executive Document 12, 47th Congress, first session, will be found a series of tests of white and yellow pine posts made at the Watertown Arsenal; and these tests probably furnish us the best information that we possess in regard to the strength of wooden columns.

The summary of results is appended:—

## COMPRESSION OF WHITE-PINE POSTS.

| No. of Test. | Weight.<br>lbs. | Average Rate of Growth.<br>rings per in. | Size of Post.      |               |               | Sectional Area.<br>sq. in. | Ultimate Strength. |                  | Manner of Failure.                        |
|--------------|-----------------|--|--------------------|---------------|---------------|----------------------------|--------------------|------------------|---|

These sets of tests furnish us practically the only reliable information we have in regard to the strength of full-size columns of white pine, yellow pine, and oak. In regard to white and yellow pine, Mr. Edward F. Ely, instructor in architecture at the Massachusetts Institute of Technology, has plotted the average, and also the lowest, results of the tables; and, from an inspection of the diagrams, he gives the following rules for determining the breaking-strength of a column with flat ends, the load being evenly distributed over the ends:—

Let  $A$  = area of section in square inches.

$f$  = constant whose value is given in the tables following.

$\frac{l}{r}$  = ratio of length to least side of rectangle, all the tests having been made on rectangular sections.

Then

$$\text{Breaking-strength} = fA,$$

where  $f$  has the following values :—

| White Pine.   |      | Yellow Pine.  |      |
|---------------|------|---------------|------|
| $\frac{l}{r}$ | $f$  | $\frac{l}{r}$ | $f$  |
| 0 to 10       | 2500 | 0 to 15       | 4000 |
| 10 to 35      | 2000 | 15 to 30      | 3500 |
| 35 to 45      | 1500 | 30 to 40      | 3000 |
| 45 to 60      | 1000 | 40 to 45      | 2500 |
|               |      | 45 to 50      | 2000 |
|               |      | 50 to 60      | 1500 |

In the case of oak, if it is desired to apply the results to greater ratios of length to diameter than those tested, a similar reduction can be made in the value of  $f$  to that which takes place here in the case of white and yellow pine.

For the ratios of length to diameter tested,  $f = 3000$  would seem to be a fair value to use.

§ 238. **Factor of Safety.**—Whereas we are constantly told, that, in the case of iron bridge-work, we should use a factor of safety 4, but that for a timber construction we should use at least 8, or even 10 and 12,—the reason evidently is, that the figures that have generally been given us for breaking-strength have been really from two to four times the actual breaking-strength,—it would seem to the writer, that, when we use correct values for breaking-strength, a factor of safety 4 will be sufficient for all ordinary timber constructions; i.e., that we should use for working-strength per square inch, one-fourth the breaking-strength per square inch. This same reasoning will also apply to the case of beams bearing a transverse load when they are designed with reference to their breaking-weight.

§ 239. **Transverse Strength of Timber.**—In this regard, the common theory of beams has already been explained in § 185 *et seq.*

The tables of Rankine and Rodman, already given, represent the values of modulus of rupture that have been in common use. Other values, not differing essentially from these, are given by Hatfield, Laslett, Thurston, Trautwine, and others, all based upon tests of small pieces. No tables of these values will be given; as those above referred to furnish practically the same information. Confining ourselves to tests of full-size pieces, we find an account of a set of tests attributed by D. K. Clark, in his "Rules and Tables," to Edwin Clark and C. Graham Smith. The results are given below, and it will be seen that they are very much below those given by experimenters on small pieces. Two tests by R. Baker are also mentioned by D. K. Clark.

During the last three years tests of the strength and stiffness of full-size beams of spruce, yellow pine, oak, and white pine, both under centre loads and distributed loads, have been carried on in the Laboratory of Applied Mechanics of the Massachusetts Institute of Technology. Tests have also been made upon the effect of time on the stiffness of such beams, also on the strength of built-up beams, and of floors and framing-joints, all full size. A summary of the results obtained will be given, and conclusions drawn as to the proper values of the modulus of rupture and modulus of elasticity, etc., to be used in practice.

Before giving this summary, the following explanation and formulæ will be appended for the convenience of those who may not have read the former part of this book. The different tables of results given in different handbooks differ in the form of the constant. Thus, the constant given by Trautwine and Hatfield is one-eighteenth the modulus of rupture, or the hypothetical breaking centre load of a beam one inch square and one foot long supported at the ends; while Rodman gives one-sixth of the modulus of rupture, or the hypothetical breaking-load at the end of a cantilever one inch square and one inch long.

The formulæ for breaking-load in terms of the modulus of rupture, and for modulus of rupture in terms of the breaking-load, for some of the most usually occurring cases of rectangular beams, are appended.

Let  $W$  = breaking-load in pounds.

$f$  = modulus of rupture in pounds per square inch.

$b$  = breadth of beam in inches.

$h$  = depth of beam in inches.

$l$  = length of beam in inches.

Then we shall have:—

(a) *Beam fixed at one end and free at the other.*

1°. Single load at free end,

$$W = f \frac{bh^2}{6l}, \quad f = \frac{6Wl}{bh^2}.$$

2°. Load uniformly distributed,

$$W = f \frac{bh^2}{3l}, \quad f = \frac{3Wl}{bh^2}.$$

(b) *Beam supported at both ends.*

1°. Single load at the middle,

$$W = \frac{4}{3} f \frac{bh^2}{l}, \quad f = \frac{3}{2} \frac{Wl}{bh^2}.$$

2°. Load uniformly distributed,

$$W = \frac{4}{3} f \frac{bh^2}{l}, \quad f = \frac{3}{4} \frac{Wl}{bh^2}.$$

3°. Single load at a distance  $a$  from the origin,

$$W = f \frac{lbh^2}{6a(l-a)}, \quad f = \frac{6Wa(l-a)}{lbh^2}.$$

#### DEFLECTION OF BEAMS.

While the preceding formulæ refer to the breaking-strength of beams, it is better engineering to determine, as the safe load of a timber beam, the load that will not deflect it more than a certain small fraction ( $\frac{1}{800}$  or  $\frac{1}{400}$ ) of the span.

Let  $W$  = given load in pounds.

$b$  = breadth in inches.

$h$  = depth in inches.

$l$  = length in inches.

$v$  = greatest deflection in inches.

$E$  = modulus of elasticity of the material in pounds per square inch.

(a) *Beam fixed at one end and free at the other.*

1°. Single load at free end,

$$v = \frac{4 W l^3}{E b h^3}, \quad E = \frac{4 W l^3}{v b h^3}.$$

2°. Load uniformly distributed,

$$v = \frac{3}{2} \frac{W l^3}{E b h^3}, \quad E = \frac{3}{2} \frac{W l^3}{v b h^3}.$$

(b) *Beam supported at both ends.*

1°. Single load at the middle,

$$v = \frac{1}{4} \frac{W l^3}{E b h^3}, \quad E = \frac{1}{4} \frac{W l^3}{v b h^3}.$$

2°. Load uniformly distributed,

$$v = \frac{5}{32} \frac{W l^3}{E b h^3}, \quad E = \frac{5}{32} \frac{W l^3}{v b h^3}.$$

The above formulæ enable us to determine the deflection of a beam under a given load when the modulus of elasticity of the material is known, or to determine the modulus of elasticity of the material from the observed deflection.

#### LONGITUDINAL SHEARING.

In any rectangular beam, the greatest intensity of the longitudinal shearing-force at any section (i.e., its intensity at the neutral axis of the section) is, if we let

$F$  = shearing-force at the section, technically so-called,  
in pounds,

$b$  = breadth of beam in inches,

$h$  = depth of beam in inches,

$$\frac{3}{2} \frac{F}{b h}.$$

In the case of a beam supported at the ends, and loaded at the middle with a single load, we have, for all sections except the middle,  $F = \frac{W}{2}$ ; and hence, if we denote by  $i$  the greatest intensity of the longitudinal shearing-force at the neutral layer, we shall have

$$i = \frac{3}{4} \frac{W}{bh} : \quad (1)$$

and this is the intensity of the shearing-force at all points along the neutral layer, except at the middle section, where it is zero.

In the case of a beam supported at the ends, with the load uniformly distributed, the greatest intensity is that at the support, and is also given by equation (1), but decreases gradually to the middle.

#### SUMMARY OF THE TESTS.

The tests recorded may be divided into six classes :—

- |                        |                       |
|------------------------|-----------------------|
| 1°. Spruce beams.      | 4°. Oak beams.        |
| 2°. Yellow-pine beams. | 5°. White-pine beams. |
| 3°. Time tests.        | 6°. Framing-joints.   |

1°. *Spruce Beams*. — Before giving a summary of the tests made in this laboratory, I will insert some of the moduli of rupture and moduli of elasticity given by different authorities.

Moduli of rupture are given as follows :—

|                   | Maximum. | Minimum. | Mean. |
|-------------------|----------|----------|-------|
| Hatfield . . . .  | 12996    | 7506     | 9900  |
| Rankine . . . .   | 12300    | 9900     | 11100 |
| Laslett . . . .   | 9707     | 7506     | 9045  |
| Trautwine . . . . | —        | —        | 8100  |
| Rodman . . . .    | —        | —        | 6168  |

Hatfield's, Laslett's, Trautwine's, and Rodman's figures are from their own experiments. Trautwine advises, for practical use, to deduct one-third on account of knots and defects, hence to use 5400. The tables show the values obtained in these tests, and I will add a recommendation as to the values of modulus of rupture and modulus of elasticity suitable to use in practice.

As a result of the tests thus far made in my laboratory, it seems to me safe to say, if our Boston lumber-yards are to be taken as a fair sample of the lumber-yards in the case of spruce, — if such lumber is ordered from a dealer of good repute, no selection being made except to discard that which is rotten or has holes in it, — that 3000 lbs. per square inch is all that could with any safety be used for a modulus of rupture, and even this might err in some cases in being too large; (2°) that, if the lumber is carefully selected at any one lumber-yard, so as to take only the best of their stock, it would not be safe to use for modulus of rupture a number greater than 4000; and if we required a lot of spruce which should have a modulus of rupture of 5000, it would be necessary to select a very few pieces from each lumber-yard in the city. With a factor of safety four, we should have for greatest allowable outside fibre stress in the three cases respectively, 750, 1000, and 1250.

The modulus of elasticity (i.e., that determined from the immediate deflections) was : maximum, 1588548; minimum, 897961; mean, 1329479.

Two time tests were made on yellow pine; and, if we should consider the effect of time on spruce the same as for yellow pine, we should obtain for use, for spruce, about 886319.

## SPRUCE BEAMS.

| No. of Test. | Width and Depth. | Distance between Supports. | Manner of Loading.                         | Breaking-Load. | Modulus of Rupture, in lbs., per Square Inch. | Modulus of Elasticity, in lbs., per Square Inch. | Remarks.                   |

*Yellow-Pine Beams.* — The moduli of rupture in common use are given as follows by different authorities ; viz., —

|                   | Maximum. | Minimum.      | Mean. |
|-------------------|----------|---------------|-------|
| Hatfield . . . .  | 21168    | 9000          | 15300 |
| Laslett . . . . . | 14162    | 10044         | 12254 |
| Trautwine . . . . | —        | { Yellow pine | 9000  |
|                   |          | { Pitch pine  | 9900  |
| Rodman . . . . .  | 9876     | 8796          | 9293  |

A summary of the figures obtained from these tests will be given in a table at the end of these remarks.

It will be observed that we have for

|                         | Maximum. | Minimum. | Mean.   |
|-------------------------|----------|----------|---------|
| Modulus of rupture . .  | 9380     | 4764     | 6984    |
| Modulus of elasticity . | 2386096  | 1256286  | 1779517 |

We also have a considerable reduction of the modulus of elasticity with time, as shown by the time tests ; the proper values for use being, in the case of spruce and hard pine, from two-thirds to three-fourths the immediate moduli of elasticity. (See p. 536.)

In regard to the modulus of rupture to be used in practice for yellow pine, I should say, that, for the *modulus of rupture* of *yellow pine* of fair quality, I should not feel justified in using a number greater than 5000 lbs. per square inch, especially for large sizes, such as 9 × 14 inches, 12 × 16 inches, etc. My reason for this conclusion is, that, although the average modulus of rupture derived from the tests already enumerated is 7292, nevertheless, we have, in the case of beam No. 59, a modulus of rupture of 5300, notwithstanding the fact that this beam was quite free from knots, cracks, crooked grain, and other defects, and had been selected by a builder as one of exceptionally good quality. With a factor of safety four, we should have about 1200 as our greatest allowable outside fibre stress.

3°. *Time Tests.* — Two time tests have been made on yellow-pine beams.

In the first the beam was 4 × 12.5 inches, 20 feet span: it remained under load from Nov. 15 to Jan. 8. It was loaded at the centre, at first with 485 lbs., which was increased on

Nov. 21 to 1289, on Nov. 25 to 2093, etc.; finally breaking with 11741 lbs., giving a modulus of rupture of 6742 lbs. per square inch. The modulus of elasticity determined from the respective deflections was as follows:—

|                                    |                      |         |
|------------------------------------|----------------------|---------|
| From immediate deflection, 1721608 | At 8525 lbs. . . . . | 1113684 |
| At 4103 lbs. . . . .               | " 9329 " . . . . .   | 1101809 |
| " 6113 " . . . . .                 | " 10133 " . . . . .  | 1108016 |
| " 7118 " . . . . .                 | " 10334 " . . . . .  | 1103987 |
| " 8123 " . . . . .                 |                      |         |
| 1377166                            |                      |         |
| 1293046                            |                      |         |
| 1157931                            |                      |         |
| 1169451                            |                      |         |

In the second time test, the beam was 4 × 12 inches, 21 feet 6 inches span, loaded at the centre.

It was loaded on Dec. 28 with 2070 lbs., which was increased to 3070 on Jan. 1; this load remaining on the beam till Jan. 30, when the load was increased until the beam broke at 11770 lbs., giving a modulus of rupture of 8019 lbs. per square inch.

The modulus of elasticity determined from the immediate deflection was 1715880 lbs. per square inch; that determined from the final deflection at 3070 lbs. was 1343918 lbs. per square inch, or about two-thirds the immediate modulus of elasticity.

A third time test, made with a distributed load on a spruce beam, has shown a similar result.

#### PROPER VALUE OF MODULUS OF ELASTICITY FOR USE IN COMPUTING DEFLECTIONS.

The fact that the strength of a structure is the strength of its weakest part, should lead us to select for use in ordinary cases, for immediate *modulus of elasticity*, a number less than the average.

Whether it is best, in any particular case, to use a number any greater than the minimum, I leave the reader to determine from the circumstances of the case and a perusal of the tests. Moreover, it should be distinctly understood, that, when the immediate modulus of elasticity is used in computing deflections, the deflections are those that will be assumed by the

beam immediately after the application of the load ; while the deflections of the beam after the load has remained on it for a certain length of time will be greater.

**MODULUS OF ELASTICITY TO BE USED IN COMPUTING THE DEFLECTIONS OF BEAMS AFTER THE LOAD HAS BEEN ON FOR SOME TIME.**

A perusal of the time tests tends to show, that, in computing the final deflection of a beam under a given load, we ought to use a modulus of elasticity no greater than three-fourths (and two-thirds would be safer) of the immediate modulus of elasticity ; and it will be noticed that the values of the immediate moduli of elasticity deduced from these tests are a little, though not very much, smaller than those given by Rankine, Trautwine, Hatfield, etc.

**4°. Oak Beams.**

**SUMMARY.**

| No. of Test. | Span.   | Width and Depth.                    | Description.   | Breaking-Weight, in lbs. | Modulus of Rupture. | Modulus of Elasticity. |
|--------------|---------|-------------------------------------|----------------|--------------------------|---------------------|------------------------|
|              | ft. in. | inches.                             |                |                          |                     |                        |

| 51           | 15 6    | 4½ × 14½                            | " " "          | 19076                    | 6060                | 1240728                |
| 55           | 13 8    | 3 × 13½                             | " " "          | 10671                    | 4984                | 853098                 |
| 80           | 18 0    | 4 × 12                              | " " "          | 13371                    | 7659                | 1307180                |
|              |         |                                     |                |                          | 4)24299             |                        |
|              |         | Average modulus of rupture . . .    |                |                          | 6075                |                        |
|              |         |                                     |                |                          |                     | 4)5169836              |
|              |         | Average modulus of elasticity . . . |                |                          |                     | 1292459                |

While the average modulus of rupture is 6075, this is evidently too high a value to use in practice. I leave the reader to judge, but I should not feel safe with more than 4000 lbs. per square inch.

5°. *White-Pine Beams.*

| 103          | 3 × 11           | 16 6    | 6588                          | 5390                | 1242649                |   |
| 104          | 3 × 11½          | 15 6    | 5088                          | 3739                | 930760                 |   |
|              |                  |         |                               | 48084               | 10842035               |   |
|              | Average          | modulus | rupture.                      | . 4808              |                        |   |
|              | Average          | modulus | elasticity                    | . . .               | 1084200                |   |

These averages become respectively, if 95 be omitted, 1062356 and 4537.

It would seem to the writer, therefore, that the rule already laid down in the case of spruce would apply also to white pine.

## LONGITUDINAL SHEARING.

Below are given tables showing the greatest intensity of the shear at the neutral axis of each beam at the time of fracture. I will give tables showing these results: and we must observe, that, in the case of those beams which gave way by shearing, the figures given represent the shearing-strength of the wood along the grain; while in the case of those that did not give way by shearing, it is fair to assume that these numbers are less than the shearing-strength of the wood.

TABLE OF BEAMS THAT GAVE WAY BY LONGITUDINAL SHEARING.

One would naturally expect to find the intensity of the shearing-stress at fracture less in the case of the beams that did not fail by shearing than in the case of those that did; and this is seen to be generally true (making allowance for different qualities) both in the case of spruce and hard pine.

The notable exceptions seem to be, in the case of spruce, beams Nos. 4, 7, 15, 16, 17, 60, 90, all of which have this intensity very large. If these be omitted from the list, the average for those that did not give way by shearing would be 160 pounds per square inch, which is less than 191, the average for those that did.

In the case of yellow pine, the notable exceptions are beams Nos. 47, 77, and 92; and, if these be omitted, the average for those yellow-pine beams that did not fail by shearing would be 197 pounds, which is less than 248.

Moreover, it is to be observed, that, in the case of the spruce, Nos. 4, 7, 15, 16, and 17 were all of smaller dimensions than those used in practice.

In the face of these apparent exceptions, which I am unable to explain, I prefer not to state at present any definite rule for the guidance of one who wishes to take the shearing-force into account in his calculations, but rather to leave him to use his judgment, in connection with these results, for any particular case.

It will also be observed that these shearing-forces are less than those obtained from the experiments on direct shearing along the grain, made at the Watertown Arsenal; and this is naturally to be expected, for the shearing in their case took place along a section that was perfectly sound, while in these cases it took place at the weakest point.

6°. *Framing-Joints*. — Another matter intimately connected with the strength of timber beams is the strength of the beam after it has been cut in some of the various ways commonly employed in framing. We are often told that a notch cut on top of a beam, or at the middle of its depth, or near the support, does but little injury; but the tests made, show the injury to be very large, amounting to a reduction of the strength of the beam to one-fourth or one-fifth of its original strength, with some of the most approved framing. The fact is, that, with a material where the shearing-strength along the grain is so small as it is in the case of timber, almost any cutting does a great deal of injury; and it is much better to avoid framing whenever it is possible, and use stirrup irons instead. In these tests, only two of the most approved framing-joints have been tested; viz., the joint known as the "tusk-and-tenon," shown

in Fig. 243, and used for framing the tail-beams of a floor into the headers, and the "double tenon and joint bolt," shown in Fig. 244, and used for framing the headers into the trimmers.

FIG. 243.

FIG. 244.

The arrangement is shown in plan in Fig. 245, where 1 and 2 are the trimmers, 3 is the header, and 4, 5, and 6 are the tail-beams; the latter being supported at one end on the header, and at the other on the wall, the header being supported by the trimmers, and the trimmers being supported on the walls at both ends.

FIG. 245.

It is sometimes the practice to hang the header in stirrup irons, and this is an improvement; but it is very seldom that the tail-beams are hung in stirrup irons, and these tests have shown the weakening already referred to, from the mortises cut in the header to admit the tail-beams.

In our earlier tests, these joints were tested by loading the header at the top, distributing the load over the mortises; and the headers then tested were made for four tail-beams. The results are given below, these headers being all of spruce:—

| No. of Test. | Span.   | Width and Depth. | Description.   | Total Breaking-Weights. |
|--------------|---------|------------------|--|-------------------------|
|              | ft. in. | in.              |  |                         |
| 2            | 6 8     | 4 × 12           | { Header. Framed at ends. Mortised for four tail-beams. Loads applied above mortises. }        | 10338                   |
| 38           | 6 8     | 6 × 12           | { Header. Framed at ends. Mortised for four tail-beams. Loads applied above mortises. }        | 10798                   |
| 39           | 6 8     | 6 × 12           | { Header. Hung in stirrup irons. Mortised for four tail-beams. Loads applied above mortises. } | 21298                   |
| 41           | 6 8     | 3½ × 12          | { Header. Framed at ends. Mortised for four tail-beams. Loads applied above mortises. }        | 107 57                  |

It is evident that the breaking-weights found here are greater than those that would actually break the header when used in a floor; for in the latter case the load is not applied at the top of the header, but lower down, and brings about an additional tendency to split the header.

A spruce floor was next built and tested, the following being a partial account of the test:—

*No. 52.*—Section of a floor between the trimmers. Spruce: three tail-beams, 2 inches by 12 inches each, framed into a 3½-inch by 11½-inch header; header in turn framed into sections of the trimmers by double tenon and joint-bolt, cross-bridged in two places; tail-beams framed by tusk-and-tenon joint, pinned, floored over and furred below; load at centre, distributed between the three tail-beams by bridging.

Span = 16 feet; weight of joist, flooring, etc., = 331 lbs.

11238 lbs. = breaking-load.

Joist on east side broke by splitting off at the tenon, bore 7988 lbs. after. The load was then increased. Centre tail-beam

broke by tension at 9988 lbs., on account of cross-grain in the lower fibres. A split also started at the lower tenon of the header, which at the time of breaking was rapidly increasing.

Average modulus of rupture of the tail-beams, including their own weight, etc., = 3801 lbs. per square inch.

Average modulus of elasticity of tail-beams = 1399141 lbs. per square inch.

It is to be noticed, that the header already began to crack when the tail-beams broke, and hence that the floor could have borne but little more, even if the load had been uniformly distributed: hence that, in this case, the breaking-strength of the floor would be determined by calculating the loads at the centre of the tail-beams, instead of accounting it as distributed; in other words, the breaking-weight would be about one-half what we should get by considering the load as distributed on the tail-beams. Since that time we have had six tests on yellow-pine headers, which will be given here.

It will be seen from these tests, that the first of these headers had for its breaking-weight 10916 lbs., and the second 13163, or in each case one-half the load on the floor. To institute a comparison, we may observe, that, if a 6-inch by 12-inch yellow-pine header 6 feet 8 inches long, with four tail-beams 18 feet long, were to support a floor, the floor surface would be 96 square feet, giving 48 square feet to be supported by the header. This, if the floor were loaded with 100 lbs. per square foot, would bring upon the header 4800 lbs., or about one-half the breaking-weight of a header only 5 feet 4 inches long; whereas, it would commonly be supposed, that, with such a construction for 100 lbs. per square foot of floor, we should have provided an unnecessarily large margin of safety.

As to the fact that the header supported in stirrup irons bore less than that which was framed, this must be due to a difference in the quality of the timber; and it would be unfair to conclude from only two tests that the second was a stronger

mode of construction than the first, even as far as the header itself is concerned.

The fact, also, that a 6-inch by 12-inch yellow-pine beam 5 feet 4 inches long bore 48000 lbs. centre load, equivalent to 96000 distributed, without breaking, while the header broke at 10916, shows what an enormous weakening is caused by cutting mortises, and how much strength would be gained by avoiding all framing, and using stirrup irons to support the tail-beams in all cases where they cannot be supported on top of the header bearing the latter.

*No. 83. — Test of yellow-pine headers.*

FIG. 246.

The headers, 6 inches by 12 inches, span 5 feet 4 inches, were hung at either end in iron stirrups, from trimmers 6 inches by 12 inches by 20 inches, which in turn were supported on jack-screws. The headers were mortised in three places (16 inches on centres) for three 3-inch by 12-inch yellow-pine tail-beams 10 feet in length.

The load was applied at the centre of the tail-beams, and divided equally among the three by iron bridging.

The tail-beams were cross-bridged in two places, 6 feet apart, by 2-inch by 3-inch spruce bridging, and also floored over with yellow-pine flooring 1 inch thick.

The weight of the tail-beams, bridging, flooring, etc., which was supported by header, was 833 lbs.

Weight of north header, 106 lbs.

Weight of south header, 122 lbs.

The headers were heart pieces, coarse grain, and sappy. The north one had a few season cracks extending from mortise to mortise on the outside. The tail-beams were of medium quality, two of them having sapwood on the edges; the third was much coarser, but contained more pitch, being heavy.

Weight of yoke and iron bridging, 366 lbs.

*Details of the Test.*

- 15366 lbs. Cracks heard in north header.
- 19866 " Loud cracks; season cracks opening in north header.
- 21366 " North header giving way, load dropped 500 lbs.; cracks  $\frac{3}{8}$  inch wide.
- 26366 " South header began to show cracks.
- 26366 " Centre tail-beam broke off below tenon at south end; load dropped 1500 lbs.

North header virtually broken at 21833 lbs., so each header bore  $\frac{21833}{2} = 10916$  lbs.

The tail-beam which did not break was heavy and full of pitch, and of a coarser grain than the other.

*No. 86.* — Test of yellow-pine headers by means of tail-beams and floor.

The headers, 6 inches by 12 inches, span 5 feet 4 inches, were mortised at each end into the trimmers with a double tenon and joint-bolt. The trimmers were supported on jack-screws, as before. Three tail-beams, 3 inches by 12 inches, span 10 feet, were mortised into the headers with tusk and tenon, and pinned.

The load was applied at the centre of tail-beams, and distributed equally over the three by means of bridging. (See No. 83.) Tail-beams cross-bridged in two places with 2-inch by 3-inch spruce, and floored over with 1-inch yellow-pine flooring.

Weight of tail-beams, bridging, flooring, etc., which was supported by headers = 763 lbs.

No deflections taken.

Weight of yoke and iron bridging, 366 lbs.

*Details of the Test.*

- 14366 lbs. North header heard to crack internally.  
24366 " Two tail-pieces began to crack under lower tenon (north end).  
24866 " A few minutes later one of them broke under tenon (north end). The headers, as far as could be seen, were uninjured.

*No. 89.* — Test of headers in floor (yellow pine). The headers and trimmers were the ones used in No. 86, and were framed in the same way. Three tail-beams, 3 inches by 12 inches, 6 feet 6 inches span (inside measurement), were framed into headers with a tusk-and-tenon joint, and then pinned.

The experiment was precisely the same as No. 86, with the exception, that, instead of 10-foot tail-beams being used, the length of these was 6 feet 6 inches.

No deflections were taken.

*Details of the Test.*

- \* 20150 lbs. Season cracks in north header began to open wider.  
\* 26325 " North header broke through the middle, following the line of mortises, then held 18825 lbs.  
South header cracked but little.

*No. 105.* — Tests of yellow-pine header in floors.

The headers and tail-beams were framed as in No. 86; and the experiment was exactly the same, with the exception that the tail-beams used were 6 feet long.

*Details of the Test.*

- 20762 lbs. Season crack in both headers opened.  
23262 " North header failed, after three minutes, through the line of mortises; while south header was but little cracked.

---

\* This weight includes half the weight of bridging, floor, and tail beams (325 lbs).

*No. 106.* — Test of yellow-pine header.

In this experiment the headers were hung in stirrup irons, exactly as in No. 83.

*Details of the Test.*

24262 lbs. Slight cracking.

26662 " East tail-beam split below line of tenon.

30262 " Held for five minutes, when west stirrup on north tail-beam broke. The header was virtually broken.

*No. 107.* — Test of yellow-pine header.

The unbroken headers of Nos. 105 and 106 were used.

*Details of the Test.*

22262 lbs. Crack in north header.

25162 " North header (framed) suddenly failed.

§ 240. *Shearing of Timber along the Grain.* — The shearing of timber always takes place along, and not across, the grain; for it can be shown, that, wherever we have a tendency to shear on a certain plane, there is an equal tendency to shear on a plane at right angles to it. Hence if there is, at any point in a piece of wood, a tendency to shear it across the grain, there must necessarily accompany it an equal tendency to shear it along the grain; and, the resistance to the latter being very slight, the timber will give way in this manner, instead of across the grain.

As to the shearing-strength per square inch, some values have been given in Rankine's table; and the following table contains results obtained at the Watertown Arsenal, and recorded in Executive Document No. 12, 47th Congress, first session.

| Kind of Wood.     | Arsenal No. | Shearing-Strength per Square Inch. | Kind of Wood.     | Arsenal No. | Shearing-Strength per Square Inch. |
|-------------------|-------------|------------------------------------|-------------------|-------------|------------------------------------|

§ 241. **General Remarks.** — A perusal of the tests on columns and on beams will show that one of the principal sources of weakness in timber is the presence of knots, and it will be noticed that the position of the fracture is in most cases determined by the knots.

Sap-wood, season cracks, and decay are doubtless other sources of weakness. The tests, however, do not present such striking evidence of the deleterious effects of the first two as is the case with knots. In general, it may be said, however, that timber used in construction should be free, or nearly free, from sap-wood; as an excessive amount of sap-wood renders it weak.

It will often be found to be a common opinion among lumber-dealers, that a piece of timber which contains the heart is not as good as one which is cut from the wood on one side of the heart. This is very often true; as the timber which is sold in the market is very liable to have cracks at the heart, and also, if the tree has passed maturity, the heart is the place where decay is likely to begin. Nevertheless, the tests of beams would not, it seems to the author, bear out the conclusion that such pieces as contain the heart are always weaker than those that do not.

Another matter that claims serious consideration is the effect of seasoning upon the strength of timber. This question can only be decided by tests on full-size pieces, as the small pieces season much more rapidly and uniformly than full-size pieces.

In this regard, the observation should be made, that practically our buildings and other constructions are built with green lumber; i.e., lumber which has been cut from three months to a year. Unless it can be shown that the seasoning which the lumber receives while in use imparts to it a greater strength, it will only be proper to consider its strength the same as that of green lumber. Not very much evidence has thus far been obtained upon this point; but, such as it is, it will be noted here.

1°. We have, on p. 505, the results of the tests of a lot of old mill columns; and, while some of them did exhibit a greater strength than green ones, a perusal of this set of tests will convince the reader that it would not be safe to rely upon any greater strength in these columns than in green ones. Moreover, these columns had been in a building heated by steam for a number of years, and during the seasoning process they had been subjected to the load they had to support. The writer has also observed some evidence of the same kind in connection with one of his time tests.

2°. In the case of beams, we have, in Nos. 60 and 66, examples of beams which had been seasoning, *unloaded*, in a building heated by steam; and in these cases there was a great gain in strength. Some yellow-pine beams exhibited a similar action. On the other hand, beams Nos. 18 and 19 had been seasoning on the wharf, in the open air, for about one year; and while some yellow-pine beams which had seasoned without load, in the building, showed great strength, in other cases the increase was not so marked.

In view of the fact that the above is practically all the evidence we have in the matter, it would seem to the writer, unless future experiments shall prove the contrary to be true, that we cannot rely, in our constructions, upon having any greater strength than that of the green lumber, and that the figures to be used should be those obtained by testing green lumber.

§ 242. **Strength of Building-Stones.** — Inasmuch as it is not intended to enter into a discussion of the work that has thus far been done in testing the strength of the ordinary building-stones, and as it will be a convenience to the reader to have some figures on which he can depend with reasonable certainty, the following table will be given, taken from Gen. Gillmore's report.

The specimens tested were cubes, 2 inches on a side: their faces were smoothed and polished, so as to obtain an even bearing.

In the following table, B means "on bed," E means "on edge."

| Kind.                   | Locality.                           | Position. | Strength<br>per Square<br>Inch. | Weight of<br>One Cubic<br>Foot. |

§ 243. **Cement Mortar.**—The reader who wishes to investigate this subject is referred, for the beginning of his research, to the treatise of Gen. Q. A. Gillmore on "Limes, Hydraulic Cements, and Mortars."

He made a large number of tests (and of these, only the following abridgment of one of his tables will be given) showing the resistance which Croton bricks cemented together cross-wise in pairs, face to face, offer to a force of traction applied at right angles to the surfaces of contact.

## CHAPTER VIII.

*CONTINUOUS GIRDERS.*

§ 244. **Fundamental Principles.** — A continuous girder is one that is continuous over one or more supports ; i.e., one that has at least one support in addition to those at the ends. The principle of continuity is, that the neutral line is throughout a continuous curve over the supports, the tangent to one branch of the curve at the support being a prolongation of the tangent to the other branch.

Whereas, in the girder supported at the ends, the bending-moment at the support is zero, in the continuous girder there is a bending-moment at the support, where the girder is continuous. There is also a shearing-force at each side of the support, the sum of the shearing-forces on the two sides of any one support forming the supporting-force.

In this chapter will be given the general methods of determining the bending-moments, slopes, and deflections of continuous girders.

1°. When the loads are distributed.

2°. When the loads are all concentrated.

3°. When there are both distributed and concentrated loads.

It is believed that the reader will thus have the means of solving all cases of continuous girders, and that, whenever it is desirable to have a set of simplified formulæ for a small but

definite number of spans, or for some special proportions or distribution of the load, he will be able to deduce such simplified formulæ from the more general ones.

§ 245. **Distributed Loads.** — In this case we assume that all the loads are distributed, whether they are uniformly distributed or not. The first step to be taken is, to find the bending-moment over each support: this is done by using what is known as the "*three-moment equation*," which we shall now proceed to deduce; and, in the course of the reasoning by which we deduce it, we shall derive a number of useful equations, expressing bending-moment, shearing-force, slope, deflection, etc., at various points.

FIG. 247.

For the purpose in view, let us assume our origin at  $O$  (Fig. 247), and let

$M_1$  = bending-moment at  $B$ .

$M_2$  = bending-moment at  $O$ .

$M_3$  = bending-moment at  $A$ .

$l_1$  =  $OA$ .

$l_{-1}$  =  $OB$ .

$F_0$  = shearing-force just to the right of  $O$ .

$F_{-0}$  = shearing-force just to the left of  $O$ .

$F_1$  = shearing-force at distance  $x$  to the right of origin.

$F_{-1}$  = shearing-force at distance  $x$  to the left of origin.

Shear is taken as positive when the tendency is to slide the part remote from the origin upwards.

If  $S_0$  = supporting-force at  $O$ ,

$$S_0 = F_0 + F_{-0}$$

Beginning, now, by taking  $O$  as origin, and  $x$  positive to the right, —

Let  $OC = x$ .

$CD = v$  = deflection at distance  $x$  from origin.

$w$  = load per unit of length (either constant, or variable with  $x$ ).

We shall then have, from the principles of the common theory of beams,

$$F_1 = F_0 - \int_0^x w dx; \quad (1)$$

i.e., the shearing-force at a distance  $x$  to the right of  $O$  is found by subtracting from the shearing-force just to the right of  $O$  the sum of the loads between the section at  $x$  and the support; and this sum is

$$\int_0^x w dx.$$

In a similar manner, if we were to take origin at  $O$ , and  $x$  positive to the left, we should have

$$F_{-1} = F_{-0} - \int_0^x w dx. \quad (2)$$

In § 204 we found the equation

$$\begin{aligned} \frac{dM}{dx} &= F_1, \\ \therefore \frac{dM}{dx} &= F_0 - \int_0^x w dx. \end{aligned}$$

Hence, integrating between  $x = 0$  and  $x = x$ , and observing, that, when  $x = 0$ ,  $M = M_0$ , we have

$$M - M_0 = F_0 x - \int_0^x \int_0^x w dx^2,$$

which reduces to

$$M = M_s + F_0x - \int_0^x \int_0^x w dx^2; \quad (3)$$

or, in words, —

The bending-moment at a distance  $x$  to the right of  $O$  is equal to the bending-moment over the support at the origin, plus the product of the shearing-force just to the right of the origin by the distance of the section from the origin, minus the sum of the moments of the loads between the section and the support about the section.

Observe that this sum of the moments of the loads between the section and the support about the section has, for its mathematical equivalent, the expression

$$\int_0^x \int_0^x w dx^2;$$

and, as a particular instance, it may be noted, that when the load is *uniformly* distributed, and hence  $w$  is constant, this will reduce to

$$\frac{wx^2}{2} = (wx) \frac{x}{2},$$

$wx$  being the load between the section and the support, and  $\frac{x}{2}$  being the leverage of its resultant.

Now write, for brevity,

$$\int_0^x \int_0^x w dx^2 = m;$$

then

$$M = M_s + F_0x - m. \quad (4)$$

Now, from § 194, we have

$$\frac{d^2v}{dx^2} = \frac{M}{EI}.$$

Let  $\alpha_1$  = slope at distance  $x$  to the right of the origin.

$\alpha_{-1}$  = slope at distance  $x$  to the left of the origin.

$\alpha_0$  = value of  $\alpha_1$  when  $x = 0$ .

$\alpha_{-0}$  = value of  $\alpha_{-1}$  when  $x = 0$ .

Then

$$\tan \alpha_1 = \frac{dv}{dx} = \int_0^x \frac{M}{EI} dx + c,$$

where  $c$  is an arbitrary constant, to be determined from the conditions of the problem.

If, now, we substitute for  $M$  its value  $M_2 + F_0 x - m$ , we shall have

$$\tan \alpha_1 = \frac{dv}{dx} = M_2 \int_0^x \frac{dx}{EI} + F_0 \int_0^x \frac{x dx}{EI} - \int_0^x \frac{m dx}{EI} + c.$$

To determine  $c$ , observe, that, when  $x = 0$ ,  $\alpha_1 = \alpha_0$ ;

$$\therefore c = \tan \alpha_0$$

$$\begin{aligned} \therefore \tan \alpha_1 = \frac{dv}{dx} &= \tan \alpha_0 + M_2 \int_0^x \frac{dx}{EI} \\ &+ F_0 \int_0^x \frac{x dx}{EI} - \int_0^x \frac{m dx}{EI}. \quad (5) \end{aligned}$$

Integrate again, and observe, that, when  $x = 0$ ,  $v = 0$ , and we obtain

$$\begin{aligned} v &= x \tan \alpha_0 + M_2 \int_0^x \int_0^x \frac{dx^2}{EI} \\ &+ F_0 \int_0^x \int_0^x \frac{x dx^2}{EI} - \int_0^x \int_0^x \frac{m dx^2}{EI}. \quad (6) \end{aligned}$$

Now write, for the sake of brevity,

$$m = \int_0^x \int_0^x w dx^2, \quad m_1 = \int_0^{l_1} \int_0^x w dx^2, \quad m_{-1} = \int_0^{l_{-1}} \int_0^x w dx^2,$$

$$n = \int_0^x \int_0^x \frac{dx^2}{EI}, \quad n_1 = \int_0^{l_1} \int_0^x \frac{dx^2}{EI}, \quad n_{-1} = \int_0^{l_{-1}} \int_0^x \frac{dx^2}{EI},$$

$$q = \int_0^x \int_0^x \frac{x dx^2}{EI}, \quad q_1 = \int_0^{l_1} \int_0^x \frac{x dx^2}{EI}, \quad q_{-1} = \int_0^{l_{-1}} \int_0^x \frac{x dx^2}{EI},$$

$$V = \int_0^x \int_0^x \frac{m dx^2}{EI}, \quad V_1 = \int_0^{l_1} \int_0^x \frac{m dx^2}{EI}, \quad V_{-1} = \int_0^{l_{-1}} \int_0^x \frac{m dx^2}{EI},$$

the last four being derived by taking  $x$  positive to the left. We shall have

$$v = x \tan \alpha_0 + M_2 n + F_0 q - V; \quad (7)$$

and, if  $v_1 =$  deflection at  $A =$  vertical height of  $A$  above  $O$ , we shall have, by substituting  $l_1$  for  $x$  in (7),

$$v_1 = l_1 \tan \alpha_0 + M_2 n_1 + F_0 q_1 - V_1.$$

Now, if we assume any horizontal datum line entirely below all the points of support, and let the height of  $B$  above this line be  $y_b$ , that of  $A$ ,  $y_a$ , and that of  $O$ ,  $y_o$ , etc., we shall have

$$y_a - y_o = l_1 \tan \alpha_0 + M_2 n_1 + F_0 q_1 - V_1. \quad (8)$$

And, if we put  $x = l_1$  in (4), we shall have

$$M_3 = M_2 + F_0 l_1 - m_1$$

$$\therefore F_0 = \frac{M_3 - M_2 + m_1}{l_1}; \quad (9)$$

and, if we substitute this value of  $F_0$  in (8), we obtain, by reducing,

$$y_a - y_o = l_1 \tan \alpha_0 + M_2 \left( n_1 - \frac{q_1}{l_1} \right) + \frac{M_3 q_1}{l_1} + \frac{m_1 q_1}{l_1} - V_1;$$

and, solving for  $\tan \alpha_o$ , we obtain

$$\tan \alpha_o = \frac{y_a - y_o}{l_1} + M_2 \left( \frac{q_1}{l_1^2} - \frac{n_1}{l_1} \right) - M_3 \frac{q_1}{l_1^2} - \frac{m_1 q_1}{l_1^2} + \frac{V_1}{l_1}. \quad (10)$$

This expression gives us the tangent of the slope at  $O$  in span  $OA$ ; and equation (9) gives us the shearing-force just to the right of  $O$  in span  $OA$ , in terms of  $M_2$ ,  $M_3$ , and known quantities.

If we were to take the origin at  $O$ , as before, and  $x$  positive to the left instead of the right, we should have, in place of (4),

$$M = M_2 + F_{-o}x - m; \quad (11)$$

in place of (9),

$$F_{-o} = \frac{M_1 - M_2 + m_{-1}}{l_{-1}}; \quad (12)$$

and in place of (10),

$$\begin{aligned} \tan \alpha_{-o} = \frac{y_b - y_o}{l_{-1}} + M_2 \left( \frac{q_{-1}}{l_{-1}^2} - \frac{n_{-1}}{l_{-1}} \right) \\ - M_1 \frac{q_{-1}}{l_{-1}^2} - \frac{m_{-1} q_{-1}}{l_{-1}^2} + \frac{V_{-1}}{l_{-1}}. \end{aligned} \quad (13)$$

But, since the girder is continuous, we must have the tangent at  $O$  to the left-hand part, a prolongation of the tangent at  $O$  to the right-hand part, as shown in Fig. 248.

Hence we must have

$$\alpha_{-o} = -\alpha_o$$

$$\therefore \tan \alpha_{-o} + \tan \alpha_o = 0.$$

Hence, adding (10) and (13), we have.

$$\begin{aligned} \frac{y_a - y_o}{l_1} + \frac{y_b - y_o}{l_{-1}} + M_2 \left\{ \frac{q_1}{l_1^2} - \frac{n_1}{l_1} + \frac{q_{-1}}{l_{-1}^2} - \frac{n_{-1}}{l_{-1}} \right\} - M_3 \frac{q_1}{l_1^2} \\ - M_1 \frac{q_{-1}}{l_{-1}^2} - \frac{m_1 q_1}{l_1^2} - \frac{m_{-1} q_{-1}}{l_{-1}^2} + \frac{V_1}{l_1} + \frac{V_{-1}}{l_{-1}} = 0; \end{aligned} \quad (14)$$

and this is the "*three-moment equation*" for the case of a distributed load, whether it be *uniformly* distributed or otherwise.

FIG. 248.

## CASE WHEN SUPPORTS ARE ON THE SAME LEVEL.

When the supports are all on the same level, then  $y_s = y_0$ , and the three-moment equation becomes

$$M_2 \left\{ \frac{q_1}{l_1^2} - \frac{n_1}{l_1} + \frac{q_{-1}}{l_{-1}^2} - \frac{n_{-1}}{l_{-1}} \right\} - \frac{M_2 q_1}{l_1^2} - \frac{M_1 q_{-1}}{l_{-1}^2} - \frac{m_1 q_1}{l_1^2} - \frac{m_{-1} q_{-1}}{l_{-1}^2} + \frac{V_1}{l_1} + \frac{V_{-1}}{l_{-1}} = 0. \quad (15)$$

## MANNER OF USING THE THREE-MOMENT EQUATION.

When the dimensions and load of the girder are known, all the quantities in the three-moment equation, whether we use (14) or (15), are known, except the three bending-moments,  $M_1$ ,  $M_2$ , and  $M_3$ .

Suppose, now, the girder to have any number of (say, seven) points of support; then, by taking the origin at  $B$  (Fig. 247), we obtain one equation between the bending-moments at  $E$ ,  $B$ , and  $O$ , the first of which, if  $E$  is an end support, is zero. Next take the origin at  $O$ , and we obtain one equation between the three bending-moments at  $B$ ,  $O$ , and  $A$ ; and so, continuing, we obtain five equations between five unknown quantities.

Solving these, we obtain the bending-moments over the supports; and from these bending-moments, after they are found, we can obtain the shearing-forces, bending-moments, slopes, and deflections, by using the equations deduced in the course of the reasoning for the three-moment equation, as equations (4), (5), (7), (9), and (10).

## SPECIAL CASE,

when, the supports being all on the same level, the load on any one span is uniformly distributed over that span, and when the girder is of uniform section throughout.

Let  $w_1$  = load per unit of length on span  $OA$ , origin at  $O$ .

$w_{-1}$  = load per unit of length on span  $OB$ , origin at  $O$ .

$I$  = the constant moment of inertia of the section

$$J_a = J_b = J_o$$

Then

$$m_1 = \frac{w_1 l_1^2}{2}, \quad m_{-1} = \frac{w_{-1} l_{-1}^2}{2};$$

$$n_1 = \frac{l_1^2}{2EI}, \quad n_{-1} = \frac{l_{-1}^2}{2EI};$$

$$q_1 = \frac{l_1^3}{6EI}, \quad q_{-1} = \frac{l_{-1}^3}{6EI};$$

$$V_1 = \frac{w_1 l_1^4}{24EI}, \quad V_{-1} = \frac{w_{-1} l_{-1}^4}{24EI}.$$

With these substitutions, the three-moment equation, either (14) or (15), becomes

$$M_{L-1} + 2M_2(l_{-1} + l_1) + M_3 l_1 + \frac{1}{4}(w_1 l_1^3 + w_{-1} l_{-1}^3) = 0. \quad (16).$$

This is a simpler form of the three-moment equation, applicable to this particular case only.

EXAMPLE I. — Suppose we have a continuous girder of uniform section, uniformly loaded, and

of three equal spans, to find  $M_a$  and  $M_c$ , also the supporting-forces, shearing-forces, bending-moments, slopes, and deflections throughout.

*Solution.* — Take the origin at  $B$ , and we have

$$M_1 = 0, \quad M_2 = M_3 = M_b = M_c;$$

since

$$l_1 = l_{-1} = l,$$

equation (16) gives

$$5M_b l + \frac{1}{4} w l^3 = 0 \quad \therefore M_b = M_c = -\frac{w l^2}{10}.$$

Next, to find the shearing-forces, we have, from (9),

$$F_b = F_c = \frac{-\frac{wl^2}{10} + \frac{wl^2}{10} + \frac{wl^2}{2}}{l} = \frac{wl}{2},$$

equals shearing-force just to the right of  $B$  or left of  $C$ .

Shearing-force just to the right of  $C$  or left of  $B =$

$$+\frac{\frac{wl^2}{10} + \frac{wl^2}{2}}{l} = \frac{3}{2}wl.$$

Hence supporting-forces are

$$S_b = S_c = \left(\frac{1}{2} + \frac{3}{2}\right)wl = 2wl,$$

$$S_a = S_d = \frac{1}{2}(3wl - 2wl) = \frac{1}{2}wl.$$

Bending-moment in span  $AB$  at distance  $x$  from  $A$ , or in span  $CD$  at distance  $x$  from  $D$ ,

$$M = \frac{1}{2}wlx - \frac{wx^2}{2}.$$

Bending-moment in middle span at a distance  $x$  from  $B$  or from  $C$ ,

$$M = -\frac{wl^2}{10} + \frac{wlx}{2} - \frac{wx^2}{2}.$$

Shearing-force in span  $AB$  or  $CD$  at a distance  $x$  from  $A$  or  $D$ ,

$$F = \frac{1}{2}wl - wx.$$

Shearing-force in middle span at distance  $x$  from  $B$  or  $C$ ,

$$F = \frac{wl}{2} - wx.$$

Maximum bending-moment in span  $BC$  (when  $x = \frac{l}{2}$ ),

$$M_o = -\frac{wl^2}{10} + \frac{wl^2}{4} - \frac{wl^2}{8} = \frac{wl^2}{40}.$$

Maximum bending-moment in span *AB* or *CD*,

$$x = \frac{2}{3}l,$$

$$M_0 = \frac{4}{25}wl^2 - \frac{4}{50}wl^2 = \frac{2wl^2}{25}.$$

Hence the greatest bending-moment to which the girder is subjected is that at *B* or *C*, and its amount is  $\frac{wl^2}{10}$ .

Slope at *B* in middle span, from equation (10),

$$\begin{aligned}\tan \alpha_B &= -\frac{wl^2}{10}\left(-\frac{l}{3EI}\right) + \frac{wl^2}{10}\left(\frac{l}{6EI}\right) - \frac{wl^3}{12EI} + \frac{wl^3}{24EI} \\ &= \frac{wl^3}{EI}\left(\frac{1}{30} + \frac{1}{60} - \frac{1}{24}\right) = \frac{wl^3}{120EI},\end{aligned}$$

which denotes an upward slope at *B* towards the right. In the same way, the girder slopes upwards at *C* towards the left. The slopes at *B* and *C* in the end spans are, of course, downwards.

Slope in the middle span at a distance *x* from *B*,

$$\tan \alpha = \frac{dv}{dx} = \frac{1}{EI}\left\{-\frac{wl^2}{10}x + \frac{wlx^2}{4} - \frac{wx^3}{6}\right\} + c.$$

When *x* = 0,

$$\tan \alpha = +\frac{wl^3}{120EI} \quad \therefore c = \frac{wl^3}{120EI}$$

$$\begin{aligned}\therefore \tan \alpha &= \frac{w}{EI}\left\{\frac{l^3}{120} - \frac{l^2x}{10} + \frac{lx^2}{4} - \frac{x^3}{6}\right\} \\ &= \frac{w}{120EI}(l^3 - 12l^2x + 30lx^2 - 20x^3)\end{aligned}$$

$$\therefore \text{Deflection} = v = \frac{w}{120EI}(l^3x - 6l^2x^2 + 10lx^3 - 5x^4).$$

In order to make plain all methods of proceeding, the slope in the end spans will be found in two different ways, as follows:—

For bending-moment, slope, and deflection in left-hand span at a distance  $x$  from  $B$  (or in the right-hand span at distance  $x$  from  $C$ ), we have

$$M = -\frac{wl^3}{10} + \frac{3}{5}wlx - \frac{wx^2}{2}.$$

$$\tan \alpha = \frac{dv}{dx} = \frac{1}{EI} \left\{ -\frac{wl^2x}{10} + \frac{3}{10}wlx^2 - \frac{wx^3}{6} \right\} + c.$$

When  $x = 0$ ,

$$\tan \alpha = -\frac{wl^3}{120EI} \quad \therefore c = -\frac{wl^3}{120EI}$$

$$\begin{aligned} \therefore \tan \alpha = \frac{dv}{dx} &= \frac{w}{EI} \left\{ -\frac{l^3}{120} - \frac{l^2x}{10} + \frac{3}{10}lx^2 - \frac{x^3}{6} \right\} \\ &= \frac{w}{120EI} (-l^3 - 12l^2x + 36lx^2 - 20x^3) \end{aligned}$$

$$\therefore \text{Deflection} = v = \frac{w}{120EI} (-l^3x - 6l^2x^2 + 12lx^3 - 5x^4).$$

We may, on the other hand, accomplish the same object by finding the slope and deflection in left-hand span at distance  $x$  from  $A$ , or in right-hand span at distance  $x$  from  $D$ , as follows:—

$$\tan \alpha = \frac{dv}{dx} = \frac{1}{EI} \int \left\{ \frac{2}{5}wlx - \frac{wx^2}{2} \right\} dx = \frac{w}{EI} \left\{ \frac{lx^2}{5} - \frac{x^3}{6} \right\} + c.$$

When  $x = l$ ,

$$\tan \alpha = \frac{wl^3}{120EI}$$

$$\therefore \frac{wl^3}{120EI} = \frac{wl^3}{30EI} + c \quad \therefore c = -\frac{wl^3}{40EI}$$

$$\begin{aligned}\therefore \tan \alpha &= \frac{dv}{dx} = \frac{w}{EI} \left\{ -\frac{l^3}{40} + \frac{lx^2}{5} - \frac{x^3}{6} \right\} \\ &= \frac{w}{120EI} \left\{ -3l^3 + 24lx^2 - 20x^3 \right\} \\ \therefore v &= \frac{w}{120EI} \left\{ -3l^3x + 8lx^3 - 5x^4 \right\}.\end{aligned}$$

The figure shows the mode of bending of the girder.

FIG. 250.

To find the greatest deflection in either span, put the expression for the slope equal to zero, and find  $x$  by the ordinary methods for solving an equation of the third degree, and then substitute this value in the expression for the deflection.

EXAMPLE II. — Continuous girder of two equal spans, section uniform, and load uniformly distributed.

FIG. 251.

*Solution.* — Take origin at  $B$ .

$$M_1 = M_3 = M_A = M_C = 0, \quad M_2 = M_B, \quad l_1 = l_2 = l, \quad w_1 = w_2 = w;$$

therefore, from equation (16),

$$4M_B l + \frac{1}{2}wl^3 = 0 \quad \therefore M_B = -\frac{wl^3}{8}.$$

Shearing-force either side of  $B =$

$$F_B = F_{-B} = \frac{wl^2}{8} + \frac{wl^2}{2} = \frac{5}{8}wl.$$

Supporting-force at  $B = \frac{5}{4}wl$ .

Supporting-force at  $A$  and  $C = \frac{3}{8}wl$ .

Shear at distance  $x$  from  $A$  or  $C$ ,

$$F = \frac{3}{8}wl - wx.$$

Bending-moment at distance  $x$  from  $A$  or  $C$ ,

$$M = \frac{3}{8}wx - \frac{wx^2}{2}.$$

Maximum bending-moment occurs when  $x = \frac{2}{3}l$ ,

$$M_o = \frac{9}{64}wl^2 - \frac{9}{128}wl^2 = \frac{9wl^2}{128}.$$

Hence greatest bending-moment to which the girder is subjected is that at  $B$ , and its magnitude is  $\frac{wl^2}{8}$ .

Slope at  $B$ , from equation (6),

$$\begin{aligned}\tan \alpha_s = \tan \alpha_{-s} &= -\frac{wl^2}{8} \left( -\frac{l}{3EI} \right) - \frac{wl^3}{12EI} + \frac{wl^3}{24EI} \\ &= \frac{wl^3}{EI} \left\{ \frac{1}{24} - \frac{1}{12} + \frac{1}{24} \right\} = 0,\end{aligned}$$

as was to be expected.

Slope at distance  $x$  from  $A$  in span  $AB$ ,

$$\tan \alpha = \frac{1}{EI} \left( \frac{3}{16}wx^2 - \frac{wx^3}{6} \right) + c.$$

When  $x = l$ ,  $\alpha = 0$ ;

$$\therefore C = -\frac{wl^3}{48EI}$$

$$\begin{aligned}\therefore \tan \alpha = \frac{dv}{dx} &= \frac{w}{EI} \left\{ \frac{3}{16}lx^2 - \frac{x^3}{6} - \frac{l^3}{48} \right\} \\ &= \frac{w}{48EI} (9lx^2 - 8x^3 - l^3).\end{aligned}$$

Deflection,

$$v = \frac{w}{48EI} (-lx + 3lx^3 - 2x^4).$$

For maximum deflection, we have

$$\frac{3}{16}lx^2 - \frac{x^3}{6} - \frac{l^3}{48} = 0$$

$$\therefore x = 0.44l.$$

$$\begin{aligned}\text{Maximum deflection} &= \frac{wl^4}{48EI} \left\{ -1 + 3(0.44)^2 - 2(0.44)^3 \right\} (0.44) \\ &= -0.0054 \frac{wl^4}{EI}.\end{aligned}$$

EXAMPLE III. — In order to solve a case where no simplifications enter, on account of symmetry or otherwise, we will take a continuous girder of five spans (as shown in the figure), the spans varying in length from 3*l* to 7*l*; the loads being uniformly distributed, and varying in intensity from 3*w* on the longest span to 7*w* on the shortest; the beam being of uniform section.

FIG. 252.

For this case we can use equation (9).

Origin at *B*,

$$0 + 14lM_B + 4lM_C + \frac{1}{4}[7w(27l^3) + 6w(64l^3)] = 0,$$

or

$$56M_B + 16M_C = -573wl^2.$$

Origin at *C*,

$$4lM_B + 18lM_C + 5lM_D + \frac{1}{4}wl^3[6(64) + 5(125)] = 0,$$

or

$$16M_B + 72M_C + 20M_D = -1009wl^2.$$

Origin at *D*,

$$5lM_C + 22lM_D + 6lM_E + \frac{1}{4}[5(125) + 4(216)]wl^3 = 0,$$

or

$$20M_C + 88M_D + 24M_E = -1489wl^2.$$

Origin at *E*,

$$6lM_D + 26lM_E + \frac{wl^3}{4}[4(216) + 3(343)] = 0,$$

or

$$24M_D + 104M_E = -1893wl^2.$$

The four equations are :

$$56M_B + 16M_C = -573wl^2. \quad (1)$$

$$16M_B + 72M_C + 20M_D = -1009wl^2. \quad (2)$$

$$20M_C + 88M_D + 24M_E = -1489wl^2. \quad (3)$$

$$24M_D + 104M_E = -1893wl^2. \quad (4)$$

Eliminate  $M_E$  between (3) and (4), and we obtain

$$130M_C + 536M_D = -6839wl^2. \quad (5)$$

Eliminate  $M_D$  between (2) and (5), and we obtain

$$2144M_B + 8998M_C = -101011wl^2. \quad (6)$$

Eliminate  $M_C$  between (1) and (6), and we obtain

$$234792M_B = -1769839wl^2. \quad (7)$$

$$\therefore M_B = -7.5379wl^2,$$

$$\therefore \text{from (1), } M_C = -9.4299wl^2,$$

$$\text{from (5), } M_D = -10.4722wl^2,$$

$$\text{from (4), } M_E = -15.7853wl^2.$$

Shearing-force just to the right of

$$A = \frac{-0 - 7.3579 + 31.5}{3}wl = 7.9874wl,$$

$$B = \frac{-9.4299 + 7.5379 + 48}{4}wl = 11.5270wl,$$

$$C = \frac{-10.4722 + 9.4299 + 62.5}{5}wl = 12.2915wl,$$

$$D = \frac{-15.7853 + 10.4722 + 72}{6}wl = 11.1145wl,$$

$$E = \frac{15.7853 + 73.5}{7}wl = 12.7550wl.$$

Shearing-force to the left of

$$B = \frac{7.5379 + 31.5}{3}wl = 13.0126wl,$$

$$C = \frac{-7.5379 + 9.4299 + 48}{4}wl = 12.4730wl,$$

$$D = \frac{-9.4299 + 10.4722 + 62.5}{5}wl = 12.7084wl,$$

$$E = \frac{-10.4722 + 15.7853 + 72}{6}wl = 12.8855wl,$$

$$F = \frac{-15.7853 + 735}{7}wl = 8.2450wl.$$

Supporting-force at

$$A = 7.9874wl, \quad C = 24.7645wl, \quad E = 25.6405wl,$$

$$B = 24.5396wl, \quad D = 23.8229wl, \quad F = 8.2450wl.$$

Shearing-force at distance  $x$  to the right of

$$A \text{ in section } AB = 7.9874wl - 7wx,$$

$$B \text{ in section } BC = 11.5270wl - 6wx,$$

$$C \text{ in section } CD = 12.2915wl - 5wx,$$

$$D \text{ in section } DE = 11.1145wl - 4wx,$$

$$E \text{ in section } EF = 12.7550wl - 3wx.$$

Bending-moment at distance  $x$  from

$$A \text{ in section } AB = + 7.9874wlx - \frac{7wx^2}{2},$$

$$B \text{ in section } BC = - 7.5379wl^2 + 11.5270wlx - \frac{6wx^2}{2},$$

$$C \text{ in section } CD = - 9.4299wl^2 + 12.2915wlx - \frac{5wx^2}{2},$$

$$D \text{ in section } DE = - 10.4722wl^2 + 11.1145wlx - \frac{4wx^2}{2},$$

$$E \text{ in section } EF = - 15.7853wl^2 + 12.7550wlx - \frac{3wx^2}{2}.$$

For the sections of maximum bending-moments (put shearing-force = 0), —

In  $AB$ ,  $x = 1.1410l$ ;

In  $BC$ ,  $x = 1.9211l$ ;

In  $CD$ ,  $x = 2.4583l$ ;

In  $DE$ ,  $x = 2.7786l$ ;

In  $EF$ ,  $x = 4.2517l$ .

Hence the maximum bending-moments are respectively, in —

Section  $AB$ ,

$$wx\left(-\frac{7x}{2} + 7.9874l\right) = +4.5570wl^2.$$

Section  $BC$ ,

$$-7.5379wl^2 + wx(11.5270l - 3x) = 3.5347wl^2.$$

Section  $CD$ ,

$$-9.4299wl^2 + wx(12.2915l - \frac{3}{2}x) = 5.6781wl^2.$$

Section  $DE$ ,

$$-10.4722wl^2 + wx(11.1145l - 2x) = 4.9693wl^2.$$

Section  $EF$ ,

$$-15.7853wl^2 + wx(12.7550l - \frac{3}{2}x) = 11.3297wl^2.$$

Values of  $\tan \alpha_0$  = slope in every case in the span, towards the right.

$$\tan \alpha_0 = M_2\left(\frac{q_1}{l_1^2} - \frac{n_1}{l_1}\right) - \frac{M_3q_1}{l_1^2} - \frac{m_1q_1}{l_1^2} + \frac{V_1}{l_1}.$$

Slope at  $B$ ,

$$\begin{aligned} \tan \alpha_B &= -7.5379 \frac{wl^3}{EI} \left(\frac{2}{3} - 2\right) + 9.4299 \left(\frac{2}{3}\right) \frac{wl^3}{EI} - \frac{32wl^3}{EI} + \frac{16wl^3}{EI} \\ &= 0.3371 \frac{wl^3}{EI}. \end{aligned}$$

Slope at C,

$$\tan \alpha_c = -9.4299 \frac{wl^3}{EI} \left( \frac{5}{6} - \frac{5}{2} \right) + 10.4722 \left( \frac{5}{6} \right) \frac{wl^3}{EI} - \frac{625}{12} \frac{wl^3}{EI} + \frac{625}{24} \frac{wl^3}{EI} = -1.5983 \frac{wl^3}{EI}.$$

Slope at D,

$$\tan \alpha_D = -10.4722 \frac{wl^3}{EI} (1 - 3) + 15.7853 \frac{wl^3}{EI} - \frac{72wl^3}{EI} + \frac{36wl^3}{EI} = 0.7297 \frac{wl^3}{EI}.$$

Slope at E,

$$\tan \alpha_E = -15.7853 \frac{wl^3}{EI} \left( \frac{7}{6} - \frac{7}{2} \right) - \frac{1029}{12} \frac{wl^3}{EI} + \frac{343}{8} \frac{wl^3}{EI} = -6.0426 \frac{wl^3}{EI}.$$

The manner of bending, very much exaggerated, is shown in the accompanying figure.

FIG. 253.

$$\text{Slope at } A = -4.096 \frac{wl^3}{EI}, \quad \text{slope at } F = +23.4578 \frac{wl^3}{EI}.$$

For the deduction, see what follows.

*Slopes in General.*

Span AB, origin at A,

$$\tan \alpha = \frac{w}{EI} \left\{ 3.9937lx^2 - \frac{7}{6}x^3 \right\} + c.$$

$$\text{When } x = 3l, \tan \alpha = 0.3371 \frac{wl^3}{EI};$$

$$\therefore \frac{wl^3}{EI} (35.9433 - 31.5) + c = 0.3371 \frac{wl^3}{EI}$$

$$\therefore c = -4.106 \frac{wl^3}{EI}$$

$$\therefore \tan \alpha = \frac{w}{EI} \left\{ 3.9937lx^2 - \frac{7}{6}x^3 - 4.106l^3 \right\}.$$

Span *BC*, origin at *B*,

$$\tan \alpha = 0.3371 \frac{wl^3}{EI} - 7.5379 \frac{wl^2x}{EI} + 5.7635 \frac{wlx^2}{EI} - \frac{wx^3}{EI}.$$

Span *CD*, origin at *C*,

$$\tan \alpha = \frac{w}{EI} \left\{ -1.5983l^3 - 9.4299l^2x + 6.1458lx^2 - \frac{5}{6}x^3 \right\}.$$

Span *DE*, origin at *D*,

$$\tan \alpha = \frac{w}{EI} \left\{ 0.7297l^3 - 10.4722l^2x + 5.55725lx^2 - \frac{2}{3}x^3 \right\}.$$

Span *EF*, origin at *E*,

$$\tan \alpha = \frac{w}{EI} \left\{ -6.0426l^3 - 15.7853l^2x + 6.3775lx^2 - \frac{wx^3}{2} \right\}.$$

When  $x = 7l$ ,

$$\tan \alpha = \frac{wl^3}{EI} (-6.0426 - 110.4971 + 312.4975 - 172.5)$$

$$= +23.4578 \frac{wl^3}{EI}.$$

*Deflections.*

Span *AB*,

$$v = \frac{w}{EI} \left\{ 1.3312lx^3 - \frac{7}{24}x^4 - 4.106l^3x \right\}.$$

Span *BC*,

$$v = \frac{w}{EI} \left\{ 0.3371l^3x - 3.7689l^2x^2 + 1.9211lx^3 - \frac{x^4}{4} \right\}.$$

Span *CD*,

$$v = \frac{w}{EI} \left\{ -1.5983l^3x - 4.7149l^2x^2 + 2.0486lx^3 - \frac{5}{24}x^4 \right\}.$$

Span *DE*,

$$v = \frac{w}{EI} \left\{ 0.7297l^3x - 5.2361l^2x^2 + 1.8524lx^3 - \frac{x^4}{6} \right\}.$$

Span *EF*,

$$v = \frac{w}{EI} \left\{ -6.0426l^3x - 7.8927l^2x^2 + 2.1258lx^3 - \frac{x^4}{8} \right\}.$$

The maximum deflections can be obtained by putting the slopes equal to zero, as before.

### § 246. Continuous Girder with Concentrated Loads.—

For our next general case, we will take that where there are no distributed loads, but where all the loads are concentrated at single points, and the section uniform throughout; and we will begin by assuming only one concentrated load on each span.

Let the support marked  $n - 1$  be the  $(n - 1)^{\text{th}}$  support, and the length of the  $(n - 1)^{\text{th}}$  span be  $l_{n-1}$ ; let the load on this span be  $W_{n-1}$ , and likewise for the other spans. Assume the origin at  $n$ , and let

$F_n$  = shearing-force just to the right of  $n$ .

$F_{-n}$  = shearing-force just to the left of  $n$ .

$F_i$  = shearing-force at distance  $x$  to the right of  $n$ .

$F_{-i}$  = shearing-force at distance  $x$  to the left of  $n$ .

Shear is taken as positive when the tendency is to slide the part remote from the origin upwards.

If  $S_n$  = supporting-force at  $n$ ,

$$S_n = F_n + F_{-n}. \quad (1)$$

Let, also,  $x_n$  = distance from origin to point of application of load  $W_n$ , and let  $x_{n-1}$  = distance from origin to point of application of load  $W_{n-1}$ .

Take  $x$  positive to the right. Then, for

$$\left. \begin{array}{l} x < x_n, \quad F_i = F_n; \\ x > x_n, \quad F_i = F_n - W_n. \end{array} \right\} \quad (2)$$

Moreover, we have

$$\frac{dM}{dx} = F_i;$$

hence, by integration, for

$$\begin{aligned} x < x_n, \quad \int_{M_n}^M dM &= \int_0^x F_n dx; \\ x > x_n, \quad \int_{M_n}^M dM &= \int_0^x F_n dx - \int_0^x W_n dx + c; \end{aligned}$$

the value of  $c$  being determined from the condition, that, when  $x = x_n$  the two results must be identical. Hence we have, for

$$\left. \begin{aligned} x < x_n, \quad M &= M_n + F_n x; \\ x > x_n, \quad M &= M_n + F_n x - W_n(x - x_n). \end{aligned} \right\} \quad (3)$$

Make  $x = l_n$  in the last equation, and we have

$$M_{n+1} = M_n + F_n l_n - W_n(l_n - x_n). \quad (4)$$

Now let  $l_n - x_n = a_n$ , and (4) becomes

$$M_{n+1} = M_n + F_n l_n - W_n a_n; \quad (5)$$

hence

$$F_n = \frac{M_{n+1} - M_n + W_n a_n}{l_n}. \quad (6)$$

Moreover, we have, as before,

$$\frac{d^2 v}{dx^2} = \frac{M}{EI} \quad \therefore EI \frac{d^2 v}{dx^2} = M,$$

$I$  being a constant.

Let, as before, —

$a_1$  = slope at distance  $x$  to the right of origin.

$a_{-1}$  = slope at distance  $x$  to the left of origin.

$a_n$  = value of  $a_1$  when  $x = 0$ .

$a_{-n}$  = value of  $a_{-1}$  when  $x = 0$ .

Then by integration, determining the constant in the same way as in (3), we have, for

$$\left. \begin{aligned} x < x_n, \quad EI(\tan \alpha_1 - \tan \alpha_n) &= M_n x + F_n \frac{x^2}{2}; \\ x > x_n, \quad EI(\tan \alpha_1 - \tan \alpha_n) &= M_n x + F_n \frac{x^2}{2} - \frac{W_n(x - x_n)^2}{2} \end{aligned} \right\} (7)$$

Hence

$$\begin{aligned} x < x_n, \quad EI \frac{dv}{dx} &= EI \tan \alpha_n + M_n x + F_n \frac{x^2}{2}; \\ x > x_n, \quad EI \frac{dv}{dx} &= EI \tan \alpha_n + M_n x + F_n \frac{x^2}{2} - \frac{W_n(x - x_n)^2}{2}. \end{aligned}$$

Integrate again, and determine constants in the same way, and for

$$\left. \begin{aligned} x < x_n, \quad E I v &= E I x \tan \alpha_n + M_n \frac{x^2}{2} + F_n \frac{x^3}{6}; \\ x > x_n, \quad E I v &= E I x \tan \alpha_n + M_n \frac{x^2}{2} + F_n \frac{x^3}{6} - \frac{W_n(x - x_n)^3}{6} \end{aligned} \right\} (8)$$

Make  $x = l_n$  in the last equation, and denote the heights of the supports above the datum line in the same way as in § 245, and we have

$$EI(y_{n+1} - y_n) = EI l_n \tan \alpha_n + M_n \frac{l_n^2}{2} + F_n \frac{l_n^3}{6} - \frac{W_n(l_n - x_n)^3}{6}. \quad (9)$$

Substitute for  $l_n - x_n$ ,  $a_n$ , and for  $F_n$ , its value from (6), and we have

$$EI(y_{n+1} - y_n) = EI l_n \tan \alpha_n + M_n \frac{l_n^2}{3} + M_{n+1} \frac{l_n^2}{6} + \frac{W_n a_n}{6} (l_n^2 - a_n^2). \quad (10)$$

Hence

$$\begin{aligned} EI \tan \alpha_n + \frac{l_n}{6} (2M_n + M_{n+1}) + \frac{W_n a_n}{6 l_n} (l_n^2 - a_n^2) \\ = EI \frac{(y_{n+1} - y_n)}{l_n}. \end{aligned} \quad (11)$$

Now, if we take origin at  $n$  and  $x$  positive to the left, we should obtain, instead of (11),

$$EI \tan \alpha_n + \frac{l_{n-1}}{6}(2M_n + M_{n-1}) + \frac{W_{n-1}a_{n-1}}{6l_{n-1}}(l_{n-1}^2 - a_{n-1}^2) = EI \left( \frac{y_{n-1} - y_n}{l_{n-1}} \right). \quad (12)$$

Now add (11) and (12), and observe, that, since the girder is continuous,

$$\tan \alpha_n + \tan \alpha_{n-1} = 0,$$

and we obtain

$$\begin{aligned} \frac{M_n}{3}(l_n + l_{n-1}) + M_{n-1} \frac{l_{n-1}}{6} + \frac{M_{n+1}l_n}{6} \\ + \frac{W_n a_n}{6l_n}(l_n^2 - a_n^2) + \frac{W_{n-1}a_{n-1}}{6l_{n-1}}(l_{n-1}^2 - a_{n-1}^2) \\ = EI \left\{ \frac{y_{n+1} - y_n}{l_n} + \frac{y_{n-1} - y_n}{l_{n-1}} \right\}; \quad (13) \end{aligned}$$

and this is the "three-moment equation" for the case of a single concentrated load on each span, and a uniform section.

When the supports are all on the same level, this becomes

$$\begin{aligned} \frac{M_n}{3}(l_n + l_{n-1}) + M_{n-1} \frac{l_{n-1}}{6} + \frac{M_{n+1}l_n}{6} + \frac{W_n a_n}{6l_n}(l_n^2 - a_n^2) \\ + \frac{W_{n-1}a_{n-1}}{6l_{n-1}}(l_{n-1}^2 - a_{n-1}^2) = 0. \quad (14) \end{aligned}$$

Either of these equations can be used (when it is applicable) just as the three-moment equation was used in the case of distributed loads.

CASE OF MORE THAN ONE LOAD ON EACH SPAN.

When there is more than one load on each span, the three-moment equation becomes as follows :—

$$\begin{aligned} \frac{M_n}{3}(l_n + l_{n-1}) + M_{n-1}\frac{l_{n-1}}{6} + M_{n+1}\frac{l_n}{6} \\ + \sum \frac{W_n a_n}{6l_n}(l_n^2 - a_n^2) + \sum \frac{W_{n-1} a_{n-1}}{6l_{n-1}}(l_{n-1}^2 - a_{n-1}^2) \\ = EI \left\{ \frac{y_{n+1} - y_n}{l_n} + \frac{y_{n-1} - y_n}{l_{n-1}} \right\}. \quad (15) \end{aligned}$$

In using these equations for concentrated loads, we can determine the moments over the supports; but we must observe, that, in getting slopes and deflections, bending-moments, etc., the algebraic expressions that represent them are different on the two sides of any one load, and hence we must deduce new values whenever we pass a load, determining the constants for our integration to correspond.

EXAMPLE. — Given a continuous girder of three spans, the middle span = 20 feet, each end span = 15 feet; supports on same level. The only loads on the girder are two; viz., a load of 5000 lbs. at 5 feet from the left-hand end, and one of 4000 lbs. 5 feet from the right-hand end. The supports are lettered from left to right, *A, B, C, D*, respectively. Find the greatest bending-moment and greatest deflection.

*Solution.* — Origin at *B*,

$$\frac{M_B}{3}(20 + 15) + \frac{M_C}{6}(20) + \frac{5000 \times 5}{6 \times 15}(225 - 25) = 0. \quad (1)$$

Origin at *C*,

$$\frac{M_C}{3}(20 + 15) + \frac{M_B}{6}(20) + \frac{4000 \times 5}{6 \times 15}(225 - 25) = 0. \quad (2)$$

These reduce to

$$\left. \begin{aligned} 70M_B + 20M_C + \frac{1000000}{3} &= 0 \\ 20M_B + 70M_C + \frac{800000}{3} &= 0 \end{aligned} \right\} \therefore \begin{aligned} M_B &= -4000 \text{ foot-lbs.} \\ M_C &= -2667 \text{ foot-lbs.} \end{aligned}$$

| Shearing-forces.             | Supporting-forces. | Slopes at supports.                 |
|------------------------------|--------------------|-------------------------------------|
| $F_A = 3067, F_{-C} = -67.$  | $S_A = 3067.$      | $\tan \alpha_A = -\frac{59444}{EI}$ |
| $F_{-B} = 1934, F_C = 1511.$ | $S_B = 2000.$      | $\tan \alpha_B = +\frac{35557}{EI}$ |
| $F_B = 67, F_{-D} = 2489.$   | $S_C = 1444.$      | $\tan \alpha_C = -\frac{31111}{EI}$ |
|                              | $S_D = 2489.$      | $\tan \alpha_D = -\frac{48888}{EI}$ |

Span  $AB$ , origin at  $A$ ,

$$x < 5, M = 3067x.$$

$$x > 5, M = 3067x - 5000(x - 5) = 25000 - 1933x.$$

Maximum bending-moment occurs when  $x = 5$  and therefore  $M_0 = 15333$ .

$$x < 5, EI \tan \alpha_1 = -59444 + 1533x^2;$$

$$x > 5, EI \tan \alpha_1 = 25000x - 967x^2 + c.$$

Determine  $c$  by condition, that, when  $x = 5$ , these two become equal;

$$\therefore c = -121944;$$

$$\therefore x > 5, EI \tan \alpha_1 = -121944 + 25000x - 967x^2.$$

For deflections,

$$x < 5, E Iv = -50444x + 511x^3;$$

$$x > 5, E Iv = -121944x + 12500x^2 - 322x^3 + c.$$

Determine  $c$  from condition, that, when  $x = 15, v = 0$ ;

$$\therefore c = 103410;$$

$$\therefore x > 5, E Iv = 103410 - 121944x + 12500x^2 - 322x^3.$$

For maximum deflection, equate slope to zero, and find  $x$ .

We find it at  $x = 6.53$ .

$$\therefore EI\theta_0 = -249531.$$

Span  $BC$ , origin at  $B$ ,

$$M = -4000 + 67x,$$

$$EI \tan \alpha_1 = 35557 - 4000x + 33x^2,$$

$$EI\theta = 35557x - 2000x^2 + 11x^3.$$

For maximum deflection, equate slope to zero, and find  $x$ .

We find it at  $x = 9.78$ .

$$\therefore EI\theta_0 = 166740.$$

Span  $CD$ , origin at  $C$ ,

$$x < 10, M = -2667 + 1511x;$$

$$x > 10, M = -2667 + 1511x - 4000(x - 10) = 37333 - 2489x;$$

$$x < 10, EI \tan \alpha_1 = -31111 - 2667x + 756x^2;$$

$$x > 10, EI \tan \alpha_1 = -131055 + 37333x - 1245x^2.$$

For deflections,

$$x < 10, EI\theta = -31111x - 1334x^2 + 252x^3;$$

$$x > 10, EI\theta = -131055x + 18667x^2 - 415x^3 + c.$$

When  $x = 15$ ,  $v = 0$ ;

$$\therefore x > 10, EI\theta = -833625 - 131055x + 18667x^2 - 415x^3.$$

For maximum deflection, equate slope to zero, and find  $x$ .

We find it at  $x = 8.41$ .

$$\therefore EI\theta_0 = -24506.$$

Hence greatest bending-moment and greatest deflection are both in span  $AB$ .

Observe, that, since we have used one foot as our unit of measure, all dimensions must be taken in feet, and the value of  $E$  is also 144 times that ordinarily given.

§ 247. **Continuous Girder, with both Distributed and Concentrated Loads.**—In this case we may either calculate the bending-moments, slopes, and deflections due to each separately, and then add the results with their proper signs, or we may modify the solution that was used for the case of a distributed load, so as to extend its applicability to this case.

Let  $W$  represent any one concentrated load, and let  $x_1$  represent the distance of its point of application from the origin. Then, in the general formulæ deduced for the distributed load, make the following changes; viz.,—

1°. Instead of

$$m = \int_0^x \int_0^x w dx^2,$$

put

$$m = \int_0^x \int_0^x w dx^2 + \Sigma W(x - x_1),$$

since, as was shown,  $m$  represents the sum of the moments of the loads, between the section and the support, about the section.

2°. Instead of

$$V = \int_0^x \int_0^x \left\{ \int_0^x \int_0^x w dx^2 \right\} \frac{dx^2}{EI},$$

put

$$V = \int_0^x \int_0^x \left\{ \int_0^x \int_0^x w dx^2 \right\} \frac{dx^2}{EI} + \Sigma W \int_{x_1}^x \int_{x_1}^x \frac{(x - x_1) dx^2}{EI},$$

and make the corresponding changes in the values of  $m$ ,  $m_{-}$ ,  $V$ , and  $V_{-}$ , leaving  $n$  and  $q$  just as before; then use the same three-moment equation as before, with these substitutions, i.e.,

$$M_2 \left\{ \frac{q_1}{l_1^2} - \frac{n_1}{l_1} + \frac{q_{-1}}{l_{-1}^2} - \frac{n_{-1}}{l_{-1}} \right\} - M_3 \frac{q_1}{l_1^2} - M_1 \frac{q_{-1}}{l_{-1}^2} - \frac{m_1 q_1}{l_1^2} - \frac{m_{-1} q_{-1}}{l_{-1}^2} \\ + \frac{V_1}{l_1} + \frac{V_{-1}}{l_{-1}} + \frac{y_2 - y_0}{l_1} + \frac{y_1 - y_0}{l_{-1}} = 0.$$

## SPECIAL CASE,

when the distributed load is uniformly distributed on each span, but may be different on the different spans, and when the girder is of uniform section.

Let  $w_1$  = weight per unit of length on  $OA$ .

$w_{-1}$  = weight per unit of length on  $OB$ .

Denote by  $W_1$  any concentrated load on  $OA$  at distance  $x_1$  from  $O$ .

Denote by  $W_{-1}$  any concentrated load on  $OB$  at distance  $x_{-1}$  from  $O$ .

Then we shall have

$$m_1 = \frac{w_1 l_1^2}{2} + \Sigma W_1 (l_1 - x_1),$$

$$m_{-1} = \frac{w_{-1} l_{-1}^2}{2} + \Sigma W_{-1} (l_{-1} - x_{-1}),$$

$$V_1 = \frac{w_1 l_1^4}{24EI} + \Sigma \frac{W_1 (l_1 - x_1)^3}{6EI},$$

$$V_{-1} = \frac{w_{-1} l_{-1}^4}{24EI} + \Sigma \frac{W_{-1} (l_{-1} - x_{-1})^3}{6EI},$$

and, as before,

$$n_1 = \frac{l_1^2}{2EI}, \quad n_{-1} = \frac{l_{-1}^2}{2EI},$$

$$q_1 = \frac{l_1^3}{6EI}, \quad q_{-1} = \frac{l_{-1}^3}{6EI}.$$

Making these substitutions in the three-moment equation, and clearing fractions, we obtain for the case, when the supports are all on the same level,

$$\begin{aligned} 0 = & M_1 l_{-1} + 2M_2 (l_1 + l_{-1}) + M_3 l_1 + \frac{1}{2} (w_1 l_1^3 + w_{-1} l_{-1}^3) \\ & + \frac{1}{l_1} \Sigma \{ W_1 [l_1^2 - (l_1 - x_1)^2] (l_1 - x_1) \} \\ & + \frac{1}{l_{-1}} \Sigma \{ W_{-1} [l_{-1}^2 - (l_{-1} - x_{-1})^2] (l_{-1} - x_{-1}) \}. \end{aligned}$$

## CONCENTRATED AND DISTRIBUTED LOADS.

EXAMPLE. — Let the girder be of uniform section, of two equal spans, each being 10 feet; let the concentrated loads be

FIG. 255.

as shown in the figure, the distributed load being 96 lbs. per foot. Find the

value of  $EI$ , so that the deflection may nowhere exceed  $\frac{1}{400}$  of the span.

*Solution.* — Use equation (12); and, in deducing value of  $M_B$ , use dimensions in feet; afterwards use inches.

Origin at  $B$ ,

$$M_A = M_C = 0;$$

$$40M_B + 2\frac{3}{4}(1000 + 1000) + \frac{1}{10}\{2000(64)(6) + 1000(51)(7) + 1000(91)(3)\} = 0,$$

$$40M_B + 48000 + 139800 = 0, \text{ or } M_B = -4695 \text{ foot-lbs.},$$

or

$$M_B = -56340 \text{ inch-lbs.}, \quad M_A = M_C = 0.$$

$$m_1 = 177600,$$

$$m_{-1} = 201600,$$

$$n_1 = \frac{7200}{EI},$$

$$\frac{n_1}{l_1} = \frac{60}{EI},$$

$$n_{-1} = \frac{7200}{EI},$$

$$\frac{n_{-1}}{l_{-1}} = \frac{60}{EI}.$$

$$q_1 = \frac{288000}{EI},$$

$$\frac{q_1}{l_1^2} = \frac{20}{EI},$$

$$q_{-1} = \frac{288000}{EI},$$

$$\frac{q_{-1}}{l_{-1}^2} = \frac{20}{EI}.$$

$$V_1 = \frac{175680000}{EI}, \quad \frac{V_1}{l_1} = \frac{1464000}{EI}.$$

$$V_{-1} = \frac{193536000}{EI}, \quad \frac{V_{-1}}{l_{-1}} = \frac{1612800}{EI}.$$

$$\text{Shear right side of middle} = \frac{0 + 56340 + 177600}{120} = 1949.5,$$

$$\text{Shear left side of middle} = \frac{0 + 56340 + 201600}{120} = 2149.5;$$

$$\text{Shear left end} = \frac{-56340 + 153600}{120} = 810.5,$$

$$\text{Shear right end} = \frac{-56340 + 177600}{120} = 1010.5;$$

$$\text{Middle supporting-force} = 4099.$$

*Bending-Moments in Each Span.*Span *AB*, origin at *A*,

$$810.5x - 4x^2$$

or

$$810.5x - 4x^2 - 2000(x - 72).$$

Span *BC*, origin at *B*,

$$-56340 + 1949.5x - 4x^2,$$

$$-56340 + 1949.5x - 4x^2 - 1000(x - 36),$$

$$-56340 + 1949.5x - 4x^2 - 1000(x - 36) - 1000(x - 84).$$

To ascertain position of the greatest bending-moment, differentiate each one.

$$810.5 - 8x = 0, \quad x = 101.31;$$

$$810.5 - 8x - 2000 = 0, \quad x = \text{a minus quantity};$$

$$1949.5 - 8x = 0, \quad x = 243.69;$$

$$1949.5 - 8x - 1000 = 0, \quad x = 118.69;$$

$$1949.5 - 8x - 1000 - 1000 = 0, \quad x = \text{a minus quantity}.$$

Hence, in span *AB*, maximum bending is at the load, and its amount is

$$(810.5)(72) - 4(72)(72) = 37620.$$

Span *BC*, maximum is at right-hand load, and is

$$-56340 + 1949.5(84) - 4(84)(84) - 1000(48) = 31194.$$

## SLOPES.

Slope at *B*,

$$T = \frac{-56340}{EI}(20 - 60) - \frac{(177600)(20)}{EI} + \frac{1464000}{EI} = \frac{165600}{EI}.$$

*Slope and Deflection in Span AB.*

First part,

$$\tan \alpha = \frac{1}{EI} \left\{ 405.25x^2 - \frac{4}{3}x^3 \right\} + \tan \alpha_0,$$

 $\alpha_0$  being slope at *A*.

Second part,

$$\tan \alpha = \frac{1}{EI} \left\{ 405.25x^2 - \frac{4}{3}x^3 - 1000x + 144000x \right\} + c.$$

When  $x = 72$ ,  $\alpha$  is the same in both cases ;

$$\therefore \frac{1}{EI} \{ 1000(72)^2 - (144000)(72) \} + \tan \alpha_0 - c = 0$$

$$\therefore c = \tan \alpha_0 - \frac{5184000}{EI}.$$

When  $x = 120$ , the second value of  $\tan \alpha$  becomes  $\frac{165600}{EI}$  ;

$$\therefore \frac{1}{EI} \left\{ (405.25)(120)^2 - \frac{4}{3}(120)^3 - (1000)(120)^2 + 144000(120) \right\} + \tan \alpha_0 - \frac{5184000}{EI} = \frac{165600}{EI},$$

$$\tan \alpha_0 = \frac{1}{EI} \{ -6411600 + 5184000 + 165600 \} = -\frac{1062000}{EI},$$

$$\therefore c = -\frac{6246000}{EI}.$$

Hence slope in first part (between  $A$  and the load),

$$\tan \alpha = \frac{1}{EI} \left\{ -1062000 + 405.25x^2 - \frac{4}{3}x^3 \right\}.$$

Second part (between  $B$  and the load),

$$\tan \alpha = \frac{1}{EI} \left\{ -6246000 + 144000x - 594.75x^2 - \frac{4}{3}x^3 \right\}.$$

*Deflection.*

First part,

$$v = \frac{1}{EI} \left\{ -1062000x + 135.08x^3 - \frac{x^4}{3} \right\}.$$

Second part,

$$v = \frac{1}{EI} \left\{ -6246000x + 72000x^2 - 198.25x^3 - \frac{1}{3}x^4 \right\} + c.$$

When  $x = 120$ ,  $v = 0$ ;

$\therefore c =$

$$\frac{1}{EI} \left\{ (6246000)(120) - (72000)(120)^2 + (198.25)(120)^3 + \frac{(120)^4}{3} \right\} \\ = \frac{120}{EI} (1036800) = \frac{124416000}{EI}.$$

Point of greatest deflection is found by putting slope equal zero. Moreover, it is plain that the greatest deflection is in the first, and not the second, part.

Hence equation is

$$\frac{1}{3}x^3 - 405.25x^2 + 1062000 = 0 \\ \therefore x = 56''.77;$$

and, substituting this in the expression for the deflection, we obtain

$$v_0 = -\frac{39037720}{EI}.$$

Hence, putting  $\frac{120}{400} = \frac{39037720}{EI}$ , we obtain

$$EI = 130125733.$$

If  $E = 1400000$ ,  $I = 92.9$ ; therefore, if  $b = 3$  inches,  $h = 7$  inches.

*Slope and Deflection in Span BC.*

Portion nearest B,

$$\tan \alpha = \frac{1}{EI} \left\{ 165600 - 56340x + 974.8x^2 - \frac{4}{3}x^3 \right\}.$$

When  $x = 36$  inches, we obtain

$$\tan \alpha = \frac{1}{EI} (165600 - 2028240 + 1263341 - 62208) = -\frac{661507}{EI}.$$

Middle portion,

$$\tan \alpha = \frac{1}{EI} \left\{ -20340x + 474.75x^2 - \frac{4}{3}x^3 \right\} + c.$$

When  $x = 36$  inches, then  $\tan \alpha = \frac{661507}{EI}$ ;

$$\therefore -661507 = -732240 + 615276 - 62208 + EIc$$

$$\therefore c = -\frac{482335}{EI}$$

$$\therefore \tan \alpha = \frac{1}{EI} \left\{ -482335 - 20340x + 474.75x^2 - \frac{4}{3}x^3 \right\}.$$

When  $x = 84$  inches,

$$\begin{aligned} \tan \alpha &= \frac{1}{EI} (-482335 - 1708560 + 3349836 - 790272) \\ &= +\frac{368669}{EI}. \end{aligned}$$

Portion nearest  $C$ ,

$$i = \frac{1}{EI} \left\{ 63660x - 25x^2 - \frac{4}{3}x^3 \right\} + c.$$

When  $x = 84$  inches, then  $\tan \alpha = \frac{368669}{EI}$ ;

$$\therefore 368669 = 5347440 - 176400 - 790272 + EIc$$

$$\therefore c = -\frac{4012099}{EI}$$

$$\therefore \tan \alpha = \frac{1}{EI} \left\{ -4012099 + 63660x - 25x^2 - \frac{4}{3}x^3 \right\}.$$

When  $x = 120$  inches,

$$\tan \alpha = \frac{1}{EI} (-4012099 + 7639200 - 360000 - 2304000) = \frac{963101}{EI}.$$

*Deflection.*

Portion nearest  $B$ ,

$$v = \frac{1}{EI} \left\{ 165600x - 28170x^2 + 324.9x^3 - \frac{1}{3}x^4 \right\}.$$

When  $x = 36$  inches,

$$\begin{aligned} v &= \frac{1}{EI} (165600 - 1014120 + 421070 - 15552)(36) \\ &= -\frac{(443002)36}{EI} = -\frac{15948072}{EI}. \end{aligned}$$

Middle portion,

$$v = \frac{1}{EI} \left\{ -482335x - 10170x^2 + 158.25x^3 - \frac{1}{3}x^4 \right\} + c.$$

When  $x = 36$  inches, then  $v = -\frac{15948072}{EI}$ ;

$$\therefore -15948072 = (-482335 - 366120 + 205092 - 15552) + EIc,$$

$$\therefore c = -\frac{15289157}{EI}.$$

$$\therefore v = \frac{1}{EI} \left\{ -15289157 - 482335x - 10170x^2 + 158.25x^3 - \frac{1}{3}x^4 \right\}.$$

Greatest deflection occurs in the middle portion, and the point is given by the equation.

$$0 = -482335 - 20340x + 474.75x^2 - \frac{4}{3}x^3 = 0;$$

$$\therefore x = 71.4.$$

Greatest deflection in span  $BC$ ,

FIG. 256.

$v =$

$$\begin{aligned} \frac{1}{EI} (-15289157 - 34438719 - 51846253 + 57602105 - 8662899) \\ = -\frac{52634923}{EI}. \end{aligned}$$

Hence, putting  $\frac{120}{400} = \frac{52634923}{EI}$ , we obtain

$$EI = 175449743;$$

therefore, if  $E = 1400000$ , we have

$$I = 125.3.$$

If  $b = 3$  inches,  $h = 8$  inches.

## EXAMPLES OF CONTINUOUS GIRDERS.

1°. Let  $I$  = uniform moment of inertia of girder.

$w$  = load per unit of length uniformly distributed.

Find expressions for

- 1, the bending-moment over each support,
- 2, the supporting-forces,
- 3, the greatest bending-moment,
- 4, the slopes at the supports,
- 5, the greatest deflection,

in each of the following cases :—

- (a) Two equal spans, length  $l$ .
- (b) Three equal spans, length  $l$ .
- (c) Four equal spans, length  $l$ .
- (d) Two spans, lengths  $l_1$  and  $l_2$  respectively.
- (e) Three spans, lengths  $l_1$ ,  $l_2$ , and  $l_3$  respectively.
- (f) Four spans, lengths  $l_1$ ,  $l_2$ ,  $l_3$ , and  $l_4$  respectively.
- (g) Two equal spans ; loads per unit of length on each span,  $w_1$  and  $w_2$  respectively.
- (h) Three equal spans ; loads per unit of length on each span,  $w_1$ ,  $w_2$ , and  $w_3$  respectively.

2°. Do the same in the case where each span is loaded with a centre load  $W$ , and has no distributed load.

3°. Find greatest bending-moment and greatest deflection for a continuous girder of two spans, uniformly loaded on these two spans with load  $w$  per unit of length, and which overhang the outer supports ; the overhanging parts having lengths  $l_0$  and  $l_0$  respectively, and the same distributed load per unit of length on the overhanging parts.

## CHAPTER IX.

## EQUILIBRIUM CURVES.—ARCHES AND DOMES.

§ 248. **Loaded Chain or Cord.**—It has been already shown (§ 126), when the form of a polygonal frame is given, that the loads must be adapted, in direction and magnitude, to that form, or else the frame will not be stable. The same is true of a loaded chain or cord, which would be realized if the frame were inverted.

If a set of loads be applied which are not consistent with the equilibrium of the frame under that form, it will change its shape until it assumes a form which is in equilibrium under the applied loads.

As to the manner of finding (when a sufficient number of conditions are given) the stresses in the different members, etc., this was sufficiently explained under the head of "Frames," and will not be repeated here, as the figures speak for themselves.

In Fig. 257 the polygon *fedcbaf* is the force polygon, while the equilibrium polygon is 123456, an open polygon. A straight line joining *e* and *a* would represent the resultant of the loads.

FIG. 257.

## CHAIN WITH VERTICAL LOADS.

If all the loads are vertical, the broken line  $edcba$  becomes a straight line and vertical, as shown in Fig. 258*b*. Whenever the loads are concentrated at single points, as 2, 3, 4, 5, the form of the chain is polygonal; and when the load is distributed, it becomes a curve, as shown in Fig. 259.

FIG. 258.

## CURVED CHAIN WITH A VERTICAL DISTRIBUTED LOAD.

Given the form of the chain  $AOE$  supported at  $A$  and  $E$ , and the total load upon it ( $bc$ , Fig. 259*b*), to find the distribution of the load graphically. First lay off  $bc$  to scale, to represent the total load: this is balanced by the two supporting-forces at  $A$  and  $E$  respectively, as shown in the figure. Hence draw  $ca$  parallel to the tangent at  $E$ , and  $ba$  parallel to that at  $A$ , and we have the force polygon  $abca$ ; the equilibrium curve being the chain  $AOE$  itself. Moreover, if the lowest point of the chain be  $O$ , then the load must be so distributed that the portion between  $O$  and  $A$  shall be balanced by the tension at  $O$  and that at  $A$ , and hence that its resultant shall pass through the intersection of the tangents at  $O$  and  $A$ . Its amount will be found by drawing from  $a$  a horizontal line; and then we shall have  $ao$  as the tension at  $a$ ,  $ab$  as the tension at  $A$ , and  $bo$  as the load between  $A$  and  $O$ . Hence the load between  $E$  and  $O$  will be  $oc$ .

FIG. 259.

Moreover, the load between  $O$  and any point, as  $B$ , will be balanced by the tension at  $O$ , and the tension at  $B$ , and hence will be  $od$ , where  $ad$  is drawn parallel to the tangent  $BD$ , so that the load between  $b$  and  $c$  will be  $dc$ ; and in this way we see that we can find the tension at any point of the chain by simply drawing a line from  $a$ , parallel to the tangent at that point, till it meets the load-line  $bc$ .

It is to be observed, that, if the tension at any point of the chain be resolved into horizontal and vertical components, the horizontal component will, when the loads are all vertical, be a constant, and the vertical component will be equal to the portion of the load between the lowest point and the point in question.

If we assume our origin at  $O$ , axis of  $x$  horizontal and axis of  $y$  vertical, and let the co-ordinates of  $B$  be  $x$  and  $y$ , and if  $w$  be the intensity of the load at the point  $(x, y)$ , we shall have, for the load  $od$  between  $O$  and  $B$ ,

$$P = \int_0^x w dx;$$

and, since the angle  $oad = \text{angle } BDC$ , we shall have

$$\frac{dy}{dx} = \frac{BC}{DC} = \frac{od}{oa} = \frac{P}{H}.$$

By differentiation, we shall have

$$\frac{d^2y}{dx^2} = \frac{\left(\frac{dP}{dx}\right)}{H}$$

or

$$\frac{d^2y}{dx^2} = \frac{w}{H}, \quad (1)$$

and this is the equation for all vertically loaded cords.

From it we can find the form of the cord to suit a given distribution of the load.

FIG. 260.

§ 249. Chain with the Load Uniformly Distributed Horizontally.—

In this case  $w$  is a constant; and if we assume our origin at the lowest point of the chain, and use the same notation as before, we shall have

$$\frac{d^2y}{dx^2} = \frac{w}{H}$$

Hence, integrating, and observing, that, when  $x = 0$ ,  $\frac{dy}{dx} = 0$ , we have

$$\frac{dy}{dx} = \frac{wx}{H};$$

and by another integration, observing, that, when  $x = 0$ ,  $y = 0$ , we obtain

$$y = \frac{w}{2H}x^2.$$

This is the equation of a parabola; hence a chain so loaded assumes a parabolic form.

EXAMPLE I. — Given the heights of the piers for supporting a chain so loaded, above the lowest point of the chain, as 8 and 18 feet respectively, the span being 100 feet, to find the distance of the lowest point from the foot of each pier, and the equation of the curve assumed by the chain.

*Solution.* — If (with the lowest point of the chain as origin) we call  $(x_1, y_1)$  the co-ordinates of the top of the first pier, and  $(x_2, y_2)$  those of the top of the second pier, we shall have, since  $y_1 = 18$  and  $y_2 = 8$ , and since we must have

$$y = \frac{w}{2H}x^2,$$

$$18 = \frac{w}{2H}x_1^2 \quad \text{and} \quad 8 = \frac{w}{2H}x_2^2$$

$$\therefore \frac{x_1}{x_2} = \sqrt{\frac{18}{8}} = \frac{3}{2} \quad \therefore x_1 = \frac{3}{2}x_2 \quad \therefore x_1 + x_2 = \frac{5}{2}x_2;$$

but

$$x_1 + x_2 = 100 \quad \therefore \frac{5}{2}x_2 = 100 \quad \therefore x_2 = 40, \quad x_1 = 60.$$

$$\text{Hence, since } 18 = \frac{w}{2H}(60)^2$$

$$\therefore \frac{w}{2H} = \frac{18}{3600} = \frac{1}{200},$$

therefore equation of the curve is

$$y = \frac{1}{200}x^2.$$

**EXAMPLE II.** — Given the load on the above chain as 4000 lbs. per foot of horizontal length, to find the tension at the lowest point, also that at each end.

*Solution.*

$$\frac{w}{2H} = \frac{1}{200}, \quad w = 4000,$$

$$\therefore 2H = 800000 \quad \therefore H = 400000 \text{ lbs.}$$

Moreover, load between lowest point and highest pier =  $60 \times 4000 = 240000$  lbs.

Therefore tension at highest pier =

$$\begin{aligned} \sqrt{(240000)^2 + (400000)^2} &= 10000\sqrt{(24)^2 + (40)^2} \\ &= 10000\sqrt{2176} = 466480 \text{ lbs.} \end{aligned}$$

Tension at lowest pier =

$$\begin{aligned} \sqrt{(160000)^2 + (400000)^2} &= 10000\sqrt{256 + 1600} \\ &= 10000\sqrt{1856} = 437919 \text{ lbs.} \end{aligned}$$

EXAMPLE III. — Given the span of the chain as 20 feet, and its length as 25 feet, the two points of support being on the same level, to find the position of the lowest point.

§ 250. *Catenary*. — The catenary is the form of the curve of a chain, which, being of uniform section, is loaded with its own weight only, i.e., with a load uniformly distributed along the length of the chain.

To deduce the equation of the catenary: if we assume the origin, as before, at the lowest point of the curve, we shall have still the general equation

$$\frac{d^2y}{dx^2} = \frac{w}{H};$$

but  $w$  in this case is not constant.

If we let  $w_1$  = the load per unit of length of chain, we shall have

$$w = w_1 \frac{ds}{dx} = w_1 \sqrt{1 + \left(\frac{dy}{dx}\right)^2};$$

hence

$$\frac{d^2y}{dx^2} = \frac{w_1}{H} \frac{ds}{dx}.$$

Or, if we let

$$\frac{w_1}{H} = \frac{1}{m},$$

a constant,

$$\frac{d^2y}{dx^2} = \frac{1}{m} \frac{ds}{dx}, \quad (1)$$

which is the differential equation of the catenary; and we only need to integrate it to obtain the equation itself.

To do this, we have

$$\frac{d^2y}{dx^2} = \frac{1}{m} \sqrt{1 + \left(\frac{dy}{dx}\right)^2} \quad \therefore \frac{\frac{d^2y}{dx^2}}{\sqrt{1 + \left(\frac{dy}{dx}\right)^2}} = \frac{1}{m};$$

therefore, integrating, and observing, that, when  $x = 0$ ,  $\frac{dy}{dx} = 0$ , we shall have

$$\log_e \left\{ \frac{dy}{dx} + \sqrt{1 + \left( \frac{dy}{dx} \right)^2} \right\} = \frac{x}{m}$$

$$\therefore \frac{dy}{dx} + \sqrt{1 + \left( \frac{dy}{dx} \right)^2} = e^{\frac{x}{m}} \quad (2)$$

$$\therefore 1 + \left( \frac{dy}{dx} \right)^2 = e^{\frac{2x}{m}} - 2e^{\frac{x}{m}} \frac{dy}{dx} + \left( \frac{dy}{dx} \right)^2$$

$$\therefore \frac{dy}{dx} = \frac{1}{2} \left( e^{\frac{x}{m}} - e^{-\frac{x}{m}} \right) \quad \therefore y = \frac{m}{2} \left( e^{\frac{x}{m}} + e^{-\frac{x}{m}} \right) + c.$$

But, when  $x = 0$ ,  $y = 0 \quad \therefore c = -m$ ; hence the equation is

$$y = \frac{m}{2} \left( e^{\frac{x}{m}} + e^{-\frac{x}{m}} \right) - m, \quad (3)$$

and this is the equation of the catenary when the origin is taken at  $O$ , the lowest point of the chain.

If it be transferred to  $O_1$ , where  $OO_1 = m$ , the equation becomes (by putting for  $y$ ,  $y - m$ )

$$y = \frac{m}{2} \left( e^{\frac{x}{m}} - e^{-\frac{x}{m}} \right). \quad (4)$$

This is the most common form of the equation to the catenary, the origin being taken, at a distance below the lowest point of the curve equal to  $m = \frac{H}{w_1}$ , the horizontal tension divided by the weight per unit of length of chain.

To find  $x$  in terms of  $y$ , we have

$$e^{\frac{x}{m}} + \frac{1}{e^{\frac{x}{m}}} = \frac{2y}{m}$$

$$\therefore e^{\frac{2x}{m}} + 1 = \frac{2y}{m} e^{\frac{x}{m}} \qquad \therefore e^{\frac{2x}{m}} - \frac{2y}{m} e^{\frac{x}{m}} = -1.$$

Solving, we have

$$e^{\frac{x}{m}} = \frac{y}{m} \pm \sqrt{\frac{y^2}{m^2} - 1} \qquad \therefore \frac{x}{m} = \log_e \left\{ \frac{y}{m} \pm \sqrt{\frac{y^2}{m^2} - 1} \right\}$$

$$\therefore x = m \log_e \left\{ \frac{y}{m} \pm \sqrt{\frac{y^2}{m^2} - 1} \right\}. \quad (5)$$

To find the length of the rope : from the equation

$$y = \frac{m}{2} \left( e^{\frac{x}{m}} + e^{-\frac{x}{m}} \right)$$

we obtain

$$\frac{dy}{dx} = \frac{1}{2} \left( e^{\frac{x}{m}} - e^{-\frac{x}{m}} \right)$$

$$\begin{aligned} \frac{ds}{dx} &= \sqrt{1 + \left( \frac{dy}{dx} \right)^2} = \sqrt{1 + \frac{1}{4} \left( e^{\frac{2x}{m}} - 2 + e^{-\frac{2x}{m}} \right)} \\ &= \sqrt{\frac{1}{4} \left( e^{\frac{2x}{m}} + 2 + e^{-\frac{2x}{m}} \right)} = \frac{1}{2} \left( e^{\frac{x}{m}} + e^{-\frac{x}{m}} \right) \end{aligned}$$

$$\therefore \frac{ds}{dx} = \frac{1}{2} \left( e^{\frac{x}{m}} + e^{-\frac{x}{m}} \right) \quad (6)$$

$$\therefore s = \frac{1}{2} \int_0^x \left( e^{\frac{x}{m}} + e^{-\frac{x}{m}} \right) dx = \frac{m}{2} \left( e^{\frac{x}{m}} - e^{-\frac{x}{m}} \right). \quad (7)$$

To find the area  $OO_1AB$ , we have

$$\text{Area} = \int_0^x y dx = \frac{m}{2} \int_0^x \left( e^{\frac{x}{m}} + e^{-\frac{x}{m}} \right) dx = \frac{m^2}{2} \left( e^{\frac{x}{m}} - e^{-\frac{x}{m}} \right). \quad (8)$$

But

$$\text{arc } OB = \frac{m}{2} \left( e^{\frac{x}{m}} - e^{-\frac{x}{m}} \right) = s;$$

hence area  $OO,AB = ms$ .

This shows, that, if the load should be distributed in such a way as to be like a uniformly thick sheet of metal, having for one side the catenary and for the other the straight line  $O,A$ , the equilibrium curve would be a catenary.

It may be convenient to have the development of  $e^{\frac{x}{m}}$  and  $e^{-\frac{x}{m}}$ ; hence they will be written here:—

$$e^{\frac{x}{m}} = 1 + \frac{x}{m} + \frac{x^2}{m^2|2} + \frac{x^3}{m^3|3} + \frac{x^4}{m^4|4} + \text{etc.},$$

$$e^{-\frac{x}{m}} = 1 - \frac{x}{m} + \frac{x^2}{m^2|2} - \frac{x^3}{m^3|3} + \frac{x^4}{m^4|4} + \text{etc.}$$

EXAMPLE I. — Given a rope 90 feet long, spanning a horizontal distance of 75 feet; find the equation of the catenary, the sag of the rope, and the inclination of the rope at each support, supposing these to be on the same level.

§ 251. **Transformed Catenary.** — We have just seen that the catenary is the form of chain suited to a load which may be represented by a uniformly thick sheet of metal, with a horizontal extrados, provided the distance  $OO_1$  is equal to  $m$ , a definite quantity. A more general case, however, would be that of a chain loaded with a load which might be represented by a uniformly thick sheet of metal, where the length  $OO_1$  is any given quantity whatever. A chain so loaded is called a *transformed catenary*, and the catenary itself becomes a particular case of the transformed catenary.

We may deduce its equation as follows:—

FIG. 262.

Let the chain be represented by  $ACB$ , and let it be so loaded that the load on  $CD$  is represented by  $w$  times area  $OCDE$ , so that  $w$  = weight per unit of area; then we shall have, for this load,

$$P = w \int_0^x y dx.$$

Hence, from what we have already seen,

$$\frac{dy}{dx} = \frac{P}{H} = \frac{w}{H} \int_0^x y dx$$

$$\therefore \frac{d^2y}{dx^2} = \frac{w}{H} y \quad \therefore \frac{dy}{dx} \frac{d^2y}{dx^2} dx = \frac{w}{H} y \frac{dy}{dx} dx.$$

Hence, integrating, we have

$$\left(\frac{dy}{dx}\right)^2 = \frac{w}{H} y^2 + c.$$

But, when  $\frac{dy}{dx} = 0$ ,  $y = a$ ;

$$\therefore c = -\frac{w}{H} a^2$$

$$\therefore \left(\frac{dy}{dx}\right)^2 = \frac{w}{H} (y^2 - a^2).$$

Or, if we write, for brevity,  $\frac{H}{w} = m^2$ , we have

$$\left(\frac{dy}{dx}\right)^2 = \frac{y^2 - a^2}{m^2} \quad \therefore \frac{dy}{dx} = \frac{1}{m} \sqrt{y^2 - a^2} \quad \therefore \frac{dy}{\sqrt{y^2 - a^2}} = \frac{dx}{m}$$

$$\therefore \log(y + \sqrt{y^2 - a^2}) = \frac{x}{m} + c.$$

But, when  $x = 0, y = a$ ;

$$\therefore \log(a) = c \qquad \therefore \log\left\{\frac{(y + \sqrt{y^2 - a^2})}{a}\right\} = \frac{x}{m}$$

$$\therefore \frac{y + \sqrt{y^2 - a^2}}{a} = e^{\frac{x}{m}} \qquad \therefore y^2 - a^2 = a^2 e^{\frac{2x}{m}} - 2aye^{\frac{x}{m}} + y^2$$

$$\therefore \frac{2y}{a} = e^{\frac{x}{m}} + e^{-\frac{x}{m}} \qquad \therefore y = \frac{a}{2}(e^{\frac{x}{m}} + e^{-\frac{x}{m}}),$$

which is the equation of the transformed catenary. This becomes the catenary itself whenever  $a = m$ .

EXAMPLE. — Given a chain loaded so that the load on  $OD$  is proportional to the area  $OEDC$ . Let  $OC = 5$  feet,  $BF = 8$  feet,  $OF = 4$  feet; weight per unit of area = 80 lbs. Find the equation of the transformed catenary, also the tension at  $C$  and that at  $B$ .

§ 252. **Linear Arch.** — In all the preceding cases, the chain or cord is called upon to resist a tensile stress arising from a load that is hung upon it. If, now, the cord be inverted, we have the proper equilibrium curve for a load placed upon it, distributed in the same manner as before; only in this latter case the cord would be subjected to direct compression throughout its whole extent. The equilibrium curve is, then, sometimes called a *linear arch*. The general equation of the equilibrium curve remains just as before,

$$\frac{d^2y}{dx^2} = \frac{w}{H},$$

the axes being so chosen that  $OX$  is horizontal and  $OY$  vertical.

Thus, if it were required to find the form of the equilibrium curve or linear arch, with the upper boundary of the loading horizontal, we should obtain a *transformed catenary*.

§ 253. **Arches.** — In the case of arches composed of a series of blocks, as in stone or brick arches, the mathematical treatment generally used for determining the proper form and proportions of the arch has been quite different from that used for the determination of the proper form and proportions of the iron arch, whether made in one piece, or two pieces hinged together, or of a lattice.

In the case of the iron arch, the treatment involves necessarily a determination of the stresses acting in all its parts, and an adaptation of its form and dimensions to the load, so that at no point shall the stress exceed the working-strength of the material.

In the case of the stone arch, it is still a question under discussion whether it would not be best to adopt the same method, although it would lead to a great deal of complexity, on account of the joints.

Nevertheless, the question usually raised is one merely of stability ; i.e., as to the proper form and dimensions to prevent, not the crushing of the stone, though this must also be taken into account if there is any danger of exceeding it, but more especially the overturning about some of the joints.

The question of the stability of the stone arch may present itself in either of the two following ways : —

1°. Given the arch and its load, to determine whether it is stable or not.

2°. Given the distribution of the load, to determine the suitable equilibrium curve, and hence the form of arch, suited to bear the given load with the greatest economy of material.

§ 254. **Modes of giving Way of Stone Arches.** — An arch may yield, (1°) by the crushing of the stone, (2°) by sliding of the joints, (3°) by overturning around a joint. The following figures show the modes of giving way of an arch by the last two methods. The first two show the dislocation of the arch by the slipping of the voussoirs. In the former case the

haunches of the arch slide out, and the crown slips down ; in the other case the reverse happens. The second two figures show the two methods by which an arch may give way by rotation of the voussoirs around the joints.

FIG. 263.

FIG. 264.

FIG. 265.

FIG. 266.

Before proceeding farther with the problem of the arch, two or three matters of a more general nature will be treated, which will be necessary in its discussion.

§ 255. *Friction.*—Let  $AB$  be a plane inclined to the horizon at an angle  $\theta$ . Let  $D$  be a body resting on the plane, of weight  $DG = W$ . Resolve  $W$  into two components,  $DE$  and  $DF$  respectively, perpendicular and parallel to the plane. The component  $DE = W \cos \theta$  is entirely neutralized by the re-action of the plane; while  $DF = W \sin \theta$ , on the other hand, is the only force tending to make the body slide down the plane. It is an experimental fact, that when the angle  $\theta$  is less than a certain angle  $\phi$ , called the angle of repose, the body does not slide; when  $\theta = \phi$ , the body is just on the point of sliding; and when  $\theta$  is greater than  $\phi$ , the body slides down the plane with an accelerated motion, showing that in this case an unbalanced force is acting. This

FIG. 267.

angle  $\phi$  depends upon the nature of the material of the plane and of the body, and on the nature of the surfaces. Hence, in the first and second cases, the friction actually developed by the normal pressure  $DE$  just balances the tangential component  $DF$ ; whereas, in the third case, when the angle of inclination of the plane to the horizon is greater than  $\phi$ , the tangential component  $DF$  is only partially balanced by the friction.

Let  $ab$  be the plane when inclined to the horizon at an angle  $\phi$ . The body is then just on the point of sliding, hence the component  $df = W \sin \phi$  is just equal to the friction developed between the two surfaces. Moreover, if we represent by  $N$  the normal pressure  $de = W \cos \phi$  on the plane, we shall have

$$df = N \tan \phi.$$

Now, it is an experimental fact, that the friction developed between two given surfaces depends only on the normal pressure, i.e., that the friction bears a constant ratio to the normal pressure; and since, in this case, the friction just balances the tangential component  $df = N \tan \phi$ , the friction due to the normal pressure  $N$  is

$$N \tan \phi.$$

Now, it makes no difference what be the position of the plane surface: if a normal pressure  $N$  be exerted, the friction that is capable of being exerted to resist any force  $F$  tangential to the plane, tending to make the bodies slide upon each other, is  $N \tan \phi$ ; and if the force  $F$  is greater than  $N \tan \phi$ , the bodies will slide, but if  $F$  is less than  $N \tan \phi$ , they will not slide. The quantity  $\tan \phi$  is called the co-efficient of friction, and will be denoted by  $f$ .

FIG. 268.

From the preceding it is evident, that, if the resultant pressure on the body makes with the normal to the plane an angle less than the angle of repose, the sliding will not take place ; whereas, if the resultant force makes with the normal to that plane an angle greater than the angle of repose, the body will slide.

§ 256. **Stability of Position.**—To determine under what conditions the stability of the block *DGHF* is secure against turning around the edge *D*: if the resultant of the weight of the block and the pressure thereon pass outside the edge *D*, as *OR*<sub>1</sub>, then the block will overturn; the moment of the couple tending to overturn it being *OR*<sub>1</sub> × *DE*. If, on the other hand, it pass within the edge, as *OR*<sub>2</sub>, the block will not overturn, since the force has a tendency to turn it the opposite way around *D*. Hence, in order that a block may not overturn around an edge at a plane joint, the resultant pressure must cut the joint within the joint itself.

**FIG. 269.**

In any structure composed of blocks united at plane joints, we must have both stability of position and stability of friction at each joint, in order that the structure may not give way.

§ 257. **Stability of a Buttress about a Plane Joint.**— Let  $DCEF$  be a vertical section of a buttress, against which a strut rib or piece of framework abuts, exerting a thrust  $P = ZG = OR$ . In order that the buttress may not give way, it must fulfil the conditions of stability at each joint. Let  $AB$  be a joint. Should several pressures act against the buttress, the force  $P$  in the line  $ZO$  may be taken to represent the resultant of all the thrusts which act on the buttress above the joint  $AB$ . Let  $G$  be the centre of gravity of the part  $ABEF$ , and let  $W = OL$  be the weight of that part of the buttress. Let  $O$  be the point of intersection of the line of

direction of the thrust, and of the weight  $W$ . Draw the parallelogram  $ORNL$ . Then will  $ON$  be the resultant pressure on the joint  $AB$ : and the conditions of stability require that the resultant pressure should cut the joint  $AB$  at some point between  $A$  and  $B$ , and that its line of direction should make with the normal to  $AB$  an angle less than the angle of repose,  $\phi$ ; and, in order that the buttress may not give way, these conditions must be fulfilled at each and every joint.

FIG. 270.

if we let  $Ar = p$ , whereas the moment of the weight which resists this is  $W(AS) = Wq$  if we let  $AS = q$ . Now, when  $ON$  passes through  $A$ , we have  $Fp = Wq$ ; when  $ON$  passes inside of  $A$ , we have  $Wq > Fp$ ; when  $ON$  passes outside of  $A$ , we have  $Wq < Fp$ . Hence the conditions of stability require that

$$Wq \geq Fp \quad \text{or} \quad Fp \leq Wq.$$

**EXAMPLE.** — Given a rectangular buttress 8 feet high, 1 foot wide, and 4 feet thick; the weight of the material being 100 lbs. per cubic foot, the buttress being composed of 8 rectangular blocks  $1 \times 4 \times 1$  foot. On this buttress is a load of 500 lbs., whose weight acts through  $K$ , where  $OK = 3$  feet. Find the greatest horizontal pressure  $P$  that can be applied along the line  $OK$ , consistent with stability, against overturning around each of the edges  $a, b, c, d, e, f, g, h$ .

FIG. 271.

*Solution.* — The weight of each block will be 400 lbs. Hence we shall have the following equations:—

$$\text{Stability about } a, \max P = \frac{1500 + 400 \times 2}{1} = 2300.$$

$$\text{" " } b, \text{ " } = \frac{1500 + 800 \times 2}{2} = 1550.$$

$$\text{" " } c, \text{ " } = \frac{1500 + 1200 \times 2}{3} = 1300.$$

$$\text{" " } d, \text{ " } = \frac{1500 + 1600 \times 2}{4} = 1175.$$

$$\text{" " } e, \text{ " } = \frac{1500 + 2000 \times 2}{5} = 1100.$$

$$\text{" " } f, \text{ " } = \frac{1500 + 2400 \times 2}{6} = 1050.$$

$$\text{" " } g, \text{ " } = \frac{1500 + 2800 \times 2}{7} = 1014.$$

$$\text{" " } h, \text{ " } = \frac{1500 + 3200 \times 2}{8} = 987.$$

The least of these being 987 lbs., it follows that the greatest pressure consistent with stability is 987 lbs.

§ 258. **Line of Resistance in a Stone Arch.** — In order to solve any problem involving the stability of a stone arch, it is necessary that the student should be able to draw a line of resistance. To make plain the meaning of the term, the following solution of an example is given. The method of drawing the line of resistance employed in this solution is given purely for purposes of illustration, and is not recommended for use in practice, as a suitable method will be given later.

**EXAMPLE.** — Given three blocks of stone of the form shown

FIG. 272.

in the figure (Fig. 272), their common thickness (perpendicular to the plane of the paper) being such that the weight per square inch of area (in the plane of the paper) is just one pound.

Given  $AC = 13$  inches,  $BC = 8$  inches. Suppose these three blocks to be kept from overturning by a horizontal force applied at the middle of  $DE$ . Find the least

value of this horizontal force consistent with stability about the inner joints, also its greatest value consistent with stability about the outer joints.

*Solution.*

$$BK = 16 \sin 15^\circ = 4.14112.$$

$$AH = 26 \sin 15^\circ = 6.72932.$$

$$CR = \frac{2}{3} \left\{ \frac{(13)^3 - (8)^3}{(13)^2 - (8)^2} \right\} = 10.7.$$

$$\text{Altitude of each trapezoid} = 5 \cos 15^\circ = 4.8296.$$

$$\text{Area of each trapezoid} = 19.5 \sin 30^\circ = 26.25 \text{ sq. in.}$$

$$\text{Weight of each stone} = 26.25 \text{ lbs.}$$

$$GG_2 = 8 \sin 30^\circ - 10.7 \cos 15^\circ \sin 15^\circ = 1.325.$$

$$KK_2 = 8 \cos 30^\circ - 10.7 \cos 15^\circ \sin 15^\circ = 4.253.$$

$$KK_3 = 10.7 \cos 15^\circ \cos 45^\circ - 8 \cos 30^\circ = 0.380.$$

$$BN_2 = 8 - 10.7 \cos 15^\circ \sin 15^\circ = 5.325.$$

$$BN_3 = 8 - 10.7 \cos 15^\circ \cos 45^\circ = 0.692.$$

$$BN_4 = 10.7 \cos 15^\circ \sin 15^\circ = 2.675.$$

$$HH_2 = 13 \cos 30^\circ - 10.7 \cos 15^\circ \sin 15^\circ = 8.583.$$

$$HH_3 = 13 \cos 30^\circ - 10.7 \cos 15^\circ \cos 45^\circ = 3.950.$$

$$\begin{aligned}
 AN_2 &= 13 - 10.7 \cos 15^\circ \sin 15^\circ &= 10.325. \\
 AN_3 &= 13 - 10.7 \cos 15^\circ \cos 45^\circ &= 5.692. \\
 AN_4 &= 13 - 10.7 \cos^2 15^\circ &= 3.017. \\
 G_1M &= 10.5 - 8 \cos 30^\circ &= 3.572. \\
 K_1M &= 10.5 - 8 \sin 30^\circ &= 6.500. \\
 CM &= 10.5 &= 10.500. \\
 H_1M &= 10.5 - 13 \sin 30^\circ &= 4.000.
 \end{aligned}$$

Let us represent the thrust at  $M$  by  $T$ . Then, to find what is the thrust required to produce equilibrium about  $G$ , we take moments about  $G$ , and likewise for the other joints. We may proceed as follows :—

INNER JOINTS.

Stability about  $G$ ,

$$T(G_1M) = (26.25)(GG_2)$$

or

$$T(3.572) = (26.25)(1.325) \quad \therefore T = 9.74.$$

Stability about  $K$ ,

$$T(K_1M) = (26.25)(KK_2 - KK_3)$$

or

$$T(6.500) = (26.25)(4.253 - 0.380) \quad \therefore T = 15.49.$$

Stability about  $B$ ,

$$T(CM) = (26.25)(BN_2 + BN_3 - BN_4) \quad \therefore T = 8.36.$$

OUTER JOINTS.

Stability about  $H$ ,

$$T(H_1M) = (26.25)(HH_2 + HH_3) \quad \therefore T = 82.25.$$

Stability about  $A$ ,

$$T(CM) = (26.25)(AN_2 + AN_3 + AN_4) \quad \therefore T = 47.59$$

It is plain, therefore, that, in order to have equilibrium, the

thrust at  $M$  must be between 15.49 lbs. and 47.59 lbs.: for, if it is less than 15.49 lbs., the arch will turn about an inner joint; and if it is greater than 47.59 lbs., it will turn around an outer joint.

FIG. 273.

If, now, we draw through  $M$  a horizontal line to meet the vertical drawn through the centre of gravity of the first stone, and lay off  $\alpha\beta = 15.49$ , and  $\alpha\gamma = 26.25$ , then will the resultant of this thrust  $\alpha\beta$  and the weight of the first stone  $\alpha\gamma$  be  $\alpha\delta$ ; this being the resultant pressure on the joint  $FG$ , its point of application being  $\epsilon$ . Next, prolong this line  $\alpha\delta$  to meet the vertical through the centre of gravity of the second stone, and combine  $\alpha\delta$  with the weight of the second stone, thus obtaining, as resultant pressure on the joint  $KH$ , the force  $\zeta\eta$ , whose point of application is at  $K$ . Compounding, now,  $\zeta\eta$  with the weight of the third stone, we obtain, as final resultant pressure on  $AB$ , the force  $\lambda\mu$  applied at  $\rho$ . Now,

joining  $M\epsilon K\rho$  by a broken line, we have the *Line of Resistance* corresponding to the thrust 15.49, or the *minimum* horizontal thrust at  $M$ . If, now, we construct a line of resistance with 47.59 lbs., we obtain the line  $M\sigma\phi A$ , corresponding to maximum horizontal thrust at  $M$ .

If the arch is in equilibrium, and if the horizontal thrust is applied at  $M$ , it is plain that the actual thrust would either be one of these two or else somewhere between these two, and hence, that, if the requisite thrust is furnished at  $M$  to keep the arch in equilibrium, the true line of resistance cannot lie outside of these two; viz., the line corresponding to maximum and that corresponding to minimum horizontal thrust at  $M$ .

If the separate stones supported loads, it would be necessary to take into account these loads, in addition to the weights of the stones, in determining the horizontal thrust, and drawing the lines of resistance.

§ 259. **Arches with Symmetrical Distribution of the Load.**—Before considering the conditions of stability of an arch, we shall proceed to some propositions about lines of resistance corresponding to maximum and minimum horizontal thrust. If, in an arch, we draw a line of resistance  $AB$  through the point  $A$  of the crown, and then, by changing the horizontal thrust, we change the line of resistance continuously till it touches the extrados of the arch at  $C'$ , we shall evidently have, in the line  $AC'B'$ , a line of resistance which has the greatest horizontal thrust of any line that passes through  $A$ , and lies wholly within the arch-ring. If, on the other hand, we decrease gradually the horizontal thrust until the line touches the intrados at  $D'$ , then we have in this line the line of minimum horizontal thrust that passes through  $A$ . By lowering the point  $A$ , however, and keeping the point  $C$  the same, we should obtain new lines of resistance with greater and greater horizontal thrust; the greatest being attained when the line comes to have one point in common with the intrados. Hence a line of maximum horizontal thrust will have one point in common with the extrados and one point in common with the intrados, the latter being above the former.

FIG. 274.

On the other hand, by retaining the point *D'* the same, and raising the point *A*, we should decrease the horizontal thrust, and thus obtain lines of resistance with less and less horizontal thrust; the least being attained when the line of resistance comes to have a point in common with the extrados. Hence the minimum line of resistance has a point in common with the extrados and one in common with the intrados, the latter being below the former.

These cases are exhibited in the following figures :—

FIG. 275.

FIG. 276.

§ 260. **Conditions of Stability.** — The question of the stability of an arch must depend upon the position of its true line of resistance. If this true line of resistance lies within the arch-ring, the arch will be stable provided the material of which it is made is incompressible. If this is not the case, the stability of the arch will depend upon how near the true line of resistance approaches the edge of the joints; for the nearer it approaches the edge of a joint, the greater the intensity of the compressive stress at that joint, and the greater the danger that the crushing-strength of the stone will be exceeded at that joint. Thus, if the true line of resistance cuts any given joint at its centre of gravity, the stress upon that joint will be uniformly distributed over the joint. If, however, it cuts the joint to one side of its centre of gravity, the intensity of the stress will be greater on that side than on the opposite side; and, if it is carried far enough to one side, we may even have tension on the other side.

§ 261. **Criterion of Safety for an Arch.**—There are two criteria of safety for an arch, that have been used:—

1°. That the line of resistance should cut each joint within such limits that the crushing-strength of the stone should not be exceeded by the stress on any part of the joint.

2°. That, inasmuch as the joint is not suited to bear tension at any point, there should be no tension to resist.

The distribution of the stress is assumed to be uniformly varying from some line in the plane of the joint. The three following figures will, on this supposition, represent the three cases:—

1°. When the stress is wholly compression.

2°. When the stress becomes zero at the edge  $B$ .

3°. When the stress becomes negative or tensile at  $B$ .

FIG. 277.

FIG. 278.

FIG. 279.

In all three figures,  $AB$  represents the joint which is assumed to be rectangular in section,  $AD$  represents the intensity of the stress at  $A$ , and  $BE$  that of the stress at  $B$ ; while  $R$  represents the point of application of the resultant stress,  $RR_1$  representing that resultant.

**PROPOSITION.**—If the stress on a rectangular joint vary uniformly from a line parallel to one edge, the condition that there shall be no tension on any part requires that the resultant of the compressive stress shall be limited to the middle third of the joint.

**PROOF.**—Let  $AB$  (Fig. 278) represent the projection of the joint on the plane of the paper. It is assumed that the

stress is uniformly varying; and, if there is to be no tension anywhere, the intensity at one edge must not have a value less than zero, hence at the limiting case the value must be zero; hence this limiting case is correctly represented by the figure, and the resultant of the compression will be for this case at the centre of stress. Thus, if  $AD$  represent the greatest intensity of the stress, then we shall have, if  $B$  be the origin and  $BA$  the axis of  $x$ , if the axis of  $y$  be perpendicular to  $AB$  at  $B$ , and if we let  $a$  = intensity of stress at a unit's distance from  $B$ , that  $RR_1 = a \int \int x dx dy$ , and  $(BR)(RR_1) = a \int \int x^2 dx dy$ ;

$$\therefore BR = \frac{\int \int x^2 dx dy}{\int \int x dx dy} = \frac{\frac{bh^3}{3}}{\frac{bh^2}{2}} = \frac{2}{3}h,$$

if  $b$  = breadth, and  $h$  =  $BA$  = height of rectangle.

Hence, if the resultant of the compression be nearer  $A$  than  $R$ , there will be tension at  $B$ ; and, on the other hand, if it be nearer  $B$  than  $\frac{2}{3}h$ , there will be tension at  $A$ . Hence follows the proposition as already stated.

While the above is probably the condition most generally used to determine the stability of an arch, at the same time, if there is any danger that the intensity of the stress at any part of any joint may exceed the working compressive strength of the stone, this ought to be examined, and hence a formula by which it may be done will be deduced.

Let  $AB$  (Fig. 279) be the joint, and let, as before,  $b$  be its breadth, and  $h$  =  $AB$  = depth; then, suppose the pressure to be uniformly varying,  $DA = f$  = the working-strength per unit of area = greatest allowable intensity of compression; then the entire stress on the joint will be represented by the triangle  $ACD$ , for the joint is incapable of resisting tension.

Hence

$$AR = \frac{1}{3}AC \quad \therefore AC = 3AR;$$

but

$$P = \frac{fb(AC)}{2} = \frac{3}{2}fb(AR) \quad \therefore AR = \frac{2}{3} \frac{P}{fb},$$

and this is the least distance from the outer edge at which the resultant should cut the joint.

We thus obtain, in terms of the pressure on any joint, and of the working-strength of the material, the limits within which the line of resistance should pass, in order that the working-strength of the stone may not be exceeded.

§ 262. **Position of the True Line of Resistance.**—The question of the most probable position of the true line of resistance involves the discussion of the properties of the elastic arch. This discussion will be given later; but, for the present, the statement only of the following proposition, due to Dr. Winkler, will be given:—

*“For an arch of constant section, that line of resistance is approximately the true one which lies nearest to the axis of the arch-ring, as determined by the method of least squares.”*

From this it will follow:—

1°. That, if a line of resistance can be drawn in the arch-ring, then the true line of resistance will lie in the arch-ring; and

2°. That, if a line of resistance can be drawn within the middle third of the arch-ring, then the true line of resistance will lie in the middle third.

But, before proving this proposition, the proposition will be used, and the method explained, for determining whether a line of resistance can be drawn within the arch-ring: for, if it can, then the true line of resistance must lie within the arch-ring; and if no line of resistance can be drawn within the arch-ring, then the true line of resistance cannot pass within the arch-ring, and the arch would necessarily be unstable, even if the materials were incompressible.

By following the same method, we could determine whether

it was possible to draw a line of resistance within the middle third of the arch-ring; and, if this is found to be possible, we should know that the true line of resistance will pass within the middle third of the arch-ring.

Hence our most usual criterion of the stability of a stone arch is, whether a line of resistance can be passed within the middle third of the arch-ring.

If the condition be used, that the working-strength of the stone for compression be not exceeded, then, instead of the middle third, we shall have some other limits.

In what follows, an explanation will be given of Dr. Scheffler's method (that most commonly employed) of determining whether a line of resistance can be drawn within the arch-ring, inasmuch as the same method can be employed to determine whether such a line can be drawn within the middle third or within any other given limits.

§ 263. **Preliminary Proposition referring to Arches Symmetrical in Form and Loading.** — *An arch and its load being given, a line of resistance can always be made to pass through any two given points; hence, if any two points of a line of resistance are given, the line is determined.*

*Proof.* — Let the arch be that shown in Fig. 281; and let us consider first the special case when the two given points are  $A$ , the top of the crown-joint, and  $G_4$ , the foot of the springing-joint. In this case, the only quantity to be determined is the thrust at  $A$ . Let this thrust be denoted by  $T$ ; let  $P$  be the total weight of the half-arch and its load; let  $a$  be the perpendicular distance of the point  $G_4$  from a vertical line through the centre of gravity of the entire half-arch and its load; let  $h$  be the vertical depth of  $G_4$  below  $A$ . Then, taking moments about  $G_4$ , we must have

$$\begin{aligned} Th &= Pa \\ \therefore T &= \frac{Pa}{h}; \end{aligned} \quad (1)$$

and the line of resistance can then be drawn with this thrust, as has been done in the figure. Next take the general case, when the given points are not in these special positions. Let them be any two points, as  $A_2$  and  $G_3$ .

In this case, the point of application of the thrust at the crown is not necessarily  $A$ , but may be some other point of the crown-joint: hence the quantities to be determined are two; viz., the thrust  $T$  at the crown, and the distance  $x$  of its point of application below  $A$ . Let the combined weight of the first two voussoirs and their load be  $P_1$ , and the horizontal distance of  $A_2$  from a vertical line through the centre of gravity of  $P_1$  be  $a_1$ .

Let  $P_2$  be the combined weight of the first three voussoirs and their load, and let  $a_2$  be the horizontal distance of  $G_3$  from a vertical line through the centre of gravity of  $P_2$ .

Let the vertical depth of  $A_2$  below  $A$  be  $h_1$ , and that of  $G_3$  below  $A$  be  $h_2$ . Then, taking moments about  $A_2$  and  $G_3$ , respectively, we shall have

$$T(h_1 - x) = P_1 a_1 \quad \text{and} \quad T(h_2 - x) = P_2 a_2,$$

two equations to determine the two unknown quantities  $T$  and  $x$ , which can easily be solved in any special case; and the resulting line of resistance can be drawn, which will pass through the two given points.

§ 264. **Dr. Scheffler's Method of Determining the Possibility of Passing a Line of Resistance within the Arch-Ring.**—In using Scheffler's method of determining whether it is possible to pass a line of resistance within the arch-ring or not, we should proceed as follows; viz.,—

First pass a line of resistance through  $I$ , the top of the crown-joint (Fig. 280), and  $e$ , the inside of the springing-joint. If this line lies wholly within the arch-ring, it proves that a line of resistance can be drawn within the arch-ring.

If this line of resistance does not pass entirely within the

arch-ring, proceed as follows: Suppose the line thus drawn to be *abcde*, passing without the arch-ring on both sides, as shown in the figure. Then from *a*, the point where it is farthest from the extrados of the arch-ring, draw a normal to the extrados, and find the point where this normal cuts the extrados: in this case, *a* is the point in question. In this way determine also the point 7, where the normal from *d* cuts the intrados; then pass a new line of resistance through the points *a* and 7, determining the thrust and its point of application. If this new line of resistance lies within the arch-ring, then it is plain that it is possible to draw a line of resistance within the arch-ring; if not, it is not at all probable that it is possible to draw such a line.

If the line of resistance drawn through 1 and *e* goes outside the arch-ring only beyond the extrados, as at *a*, we should draw our second line of resistance through *a* and *e*; if, on the other hand, it goes outside only below the intrados, as at *d*, we should draw our second line through 1 and 7.

In the construction, we make use of a slice of the arch included between two vertical planes a unit of distance apart; and we take for our unit of weight the weight of one cubic unit of the material of the voussoirs, so that the number of units of area in any portion of the face of the arch shall represent the weight of that portion of the arch.

We next draw, above the arch, a line (*DD*, in Fig. 281), straight or curved, such that the area included between any portion of it, as *D*, *D*, the two verticals at the ends of that portion, and the extrados of the arch-ring, shall represent by its area the load upon the portion of the arch immediately below it. This line will limit the load itself whenever this is of the same material as the voussoirs; otherwise it will not. We shall always call it, however, the extrados of the load.

The mode of procedure will best be made plain by the solution of examples; and two will be taken, in the first of which only one trial is necessary to construct a line of resistance that shall lie wholly within the arch-ring, and, in the second, two trials are necessary.

**EXAMPLE.**—The half-arch under consideration is shown in Fig. 281,  $GG_4$  being the intrados,  $AA_4$  the extrados of the arch,

**FIG. 281.**

and  $DD_1$  the extrados of the load. The arcs  $GG_1$  and  $AA_1$  are concentric circular arcs. The data are as follows:—

Span  $= 2(G, O) = 6.00$  feet,  
 Rise  $= GO = 0.50$  foot,  
 Thickness of voussoirs  $= AG = A_1 G_1 = 0.75$  foot,  
 Height of extrados of load above  $A = AD = 1.60$  foot.

The position of the joints is not assumed to be located. We therefore draw through  $A$  a horizontal line  $AB$ , and divide this into lengths nearly equal, unless, as is usual near the springing, there is special reason to the contrary. Thus, we make the first three lengths each equal to 1 foot, and thus reach a vertical

through  $G_4$ ; and then the last division has a length of 0.24 foot. We have thus divided the half-arch and its load into four parts; viz.,  $GDD_1H_1$ ,  $H_1D_1D_2H_2$ ,  $H_2D_2D_3G_4$ , and  $G_4D_3D_4A$ , the loads on these respective portions being represented by their areas respectively. We assume the centre of gravity of each load to lie on its middle vertical; and we then proceed to determine the numerical values of the several loads, the distances of their centres of gravity from a vertical through the crown, also the amount and centre of gravity of the first and second loads together, then of the first, second, and third, etc.

The work for this purpose is arranged as follows:—

| (1)                 | (2)     | (3)     | (4)   | (5)        | (6)     | (7)           | (8)   | (9)     | (10)       |
|---------------------|---------|---------|-------|------------|---------|---------------|-------|---------|------------|
| Number of Voussoir. | Length. | Height. | Area. | Lever Arm. | Moment. | Partial Sums. | Area. | Moment. | Lever Arm. |

Column (1) shows the number of the voussoir.

- “ (2) gives the horizontal lengths of the several trapezoids.
- “ (3) gives the middle heights of the trapezoids.
- “ (4) gives the areas of the trapezoids, and is obtained by multiplying together the numbers in (2) and (3).
- “ (5) gives the distances from  $A$  to the middle lines of the trapezoids.
- “ (6) gives the products of (4) and (5), giving the moments of the respective loads about an axis through  $A$  perpendicular to the plane of the paper.

Column (7) merely indicates the successive combinations of voussoirs.

" (8) has for its numbers, —

- 1°. The area representing the first load.
- 2°. The area representing the first two loads.
- 3°. The area representing the first three.
- 4°. The area representing the first four.

" (9) has for its numbers, —

- 1°. The moment of the first load about  $A$ .
- 2°. The moment of the first and second loads about  $A$ .
- 3°. The moment of the first, second, and third loads about  $A$ .
- 4°. The moment of the first, second, third, and fourth loads about  $A$ .

" (10) is obtained by dividing column (9) by column (8); the quotients being respectively the distance from  $A$  to the centres of gravity of the first, of the first and second, of the first, second, and third, and of the first, second, third, and fourth loads.

The calculation thus far is purely mathematical, and merely furnishes us with the loads and their points of application; in other words, furnishes us the data with which to begin our calculation of the thrust. Before passing to this, it should be said, however, that we now assume the joints to be drawn through the points  $A_1$ ,  $A_2$ ,  $A_3$ , and  $A_4$ , and generally normal to the extrados of the arch.

In this proceeding, we, of course, make an error which is very small near the crown and increases near the springing of the arch; this error, in the case of voussoir  $A_1A_2G_2G_1$ , amounts to the difference of the two triangles  $A_2G_2H_2$  and  $A_1G_1H_1$ . A manner of making a correction by moving the joint will be explained later; but now we will complete our example, as the

errors are not serious in this example. We now pass a line of resistance through  $A$ , the upper point of the crown-joint, and  $G_4$ , the lower point of the springing. For this purpose take moments about  $G_4$ ; and we shall have, if  $T$  = thrust at the crown,

$$1.25T = (5.563)(3 - 1.68),$$

since 5.563 is the whole weight, and  $3 - 1.68$  is its leverage about  $G_4$ .

Hence

$$1.25T = (5.563)(1.32) = 7.343$$

$$\therefore T = 5.87.$$

Hence we proceed to draw a line of resistance through  $A$ , assuming, as the horizontal thrust, 5.87. To do this we proceed as follows: From  $a$ , the point of intersection of  $AD$  with the vertical through the centre of gravity of the first trapezoid, we lay off  $ab$  to scale equal to 5.87, and then lay off  $bC$  vertically to scale equal to 1.57, the first load; then will  $Ca$  be the resultant pressure on joint  $A, G_1$ , and its point of application will be  $P$ , which gives us one point in the line of resistance. To obtain the point  $P_1$ , we lay off  $Aa_1 = 1.017$ , the lever arm of the first two loads; then lay off  $a_1b_1 = 5.87$ , the thrust; then lay off  $b_1C_1$ , equal to 3.25, the weight of the first two loads. Then will  $C_1a_1$  be the pressure on the second joint; and the point  $P_1$ , or its point of application, is at the intersection of  $C_1a_1$  with  $A_2G_2$ .

Then lay off  $Aa_2 = 1.563$ ,  $a_2b_2 = 5.87$ ,  $b_2C_2 = 5.150$ ; and  $P_2$ , the next point of the line of resistance, is the intersection of  $C_2a_2$  with  $A_3G_3$ . Then lay off  $Aa_3 = 1.680$ ,  $a_3b_3 = 5.87$ ,  $b_3C_3 = 5.563$ ; and  $C_3a_3$  is the pressure on the springing, and this will intersect  $A_4G_4$  at  $G_4$ , unless some mistake has been made in the work. Then is  $APP_2G_4$ , the line of resistance through  $A$  and  $G_4$ , and this lies entirely within the arch-ring.

Hence we conclude that it is possible to draw a line of resistance within the arch-ring without having recourse to another trial.

§ 265. **Scheffler's Mode of Correcting the Joints.**—The following is the approximate construction given by Scheffler for correcting the joint: Let  $DCG$  be the side of the trapezoid, and  $CH$  the uncorrected joint. From  $b$ , the middle point of  $GH$ , draw  $Db$ ; then draw  $Gc$  parallel to  $bD$ , and  $ch$  parallel to  $CH$ . Then will  $ch$  be the corrected joint.

FIG. 283.

Conversely, having given the joint  $CH$ , to find the side of the trapezoid which limits the portion of the load upon it: through  $C$  draw  $DG$  vertical; join  $D$  with  $b$ , the middle point of  $GH$ ; then draw  $Cg$  parallel to  $Db$ ; then, from  $g$ , drawing  $dg$  vertical, we thus have the desired side of the trapezoid.

FIG. 282.

§ 266. **Another Example.**—Another example will now be solved, which necessitates two trials, and where some of the joints have to be corrected. It is practically one of Scheffler's. The dimensions of the arch are as follows:—

|                                       |             |
|---------------------------------------|-------------|
| Half-span . . . . .                   | 32.97 feet. |
| Rise . . . . .                        | 24.74 feet. |
| Thickness of ring . . . . .           | 5.15 feet.  |
| Height of load at crown . . . . .     | 8.24 feet.  |
| Height of load at springing . . . . . | 33.50 feet. |

The arch may be drawn by using, for the intrados, two circular arcs. Beginning at the springing, draw a  $60^\circ$  arc with a radius of one-fourth the span; then, with an arc tangent to this arc, continue to the crown, the proper rise having been previously laid off. The work for drawing a line of resistance

through the top of the crown-joint and the inside of the springing will be given without comment. It is as follows:—

| (1)                        | (2)     | (3)     | (4)    | (5)           | (6)          | (7)           | (8)    | (9)     | (10)          |
|----------------------------|---------|---------|--------|---------------|--------------|---------------|--------|---------|---------------|
| Number of<br>the Voussoir. | Length. | Height. | Area.  | Lever<br>Arm. | Mo-<br>ment. | Partial Sums. | Area.  | Moment. | Lever<br>Arm. |
| 1                          | 8.24    | 14.1    | 116.18 | 4.12          | 476          | 1             | 116.18 | 476     | 4.12          |
| 2                          | 8.24    | 16.4    | 135.14 | 12.36         | 1675         | 1+2           | 251.32 | 2151    | 8.57          |
| 3                          | 8.24    | 18.3    | 150.79 | 20.60         | 3106         | 1+...+3       | 402.11 | 5257    | 13.09         |
| 4                          | 4.13    | 22.6    | 93.34  | 26.79         | 2600         | 1+...+4       | 495.45 | 7857    | 15.87         |
| 5                          | 4.13    | 27.1    | 111.92 | 30.92         | 3448         | 1+...+5       | 607.37 | 11305   | 18.62         |
| 6                          | 5.14    | 34.7    | 178.36 | 35.55         | 6351         | 1+...+6       | 785.73 | 17656   | 22.49         |
| —                          | —       | —       | 785.73 | —             | 17656        | —             | —      | —       | —             |

$$29.89T = (785.73)(32.97 - 22.49),$$

$$29.89T = 8234.45$$

$$\therefore T = 275.5.$$

Hence we construct the line of resistance passing through the top of the crown-joint and the inside of the springing, using the thrust 275.5.

The construction is shown in the figure, and is entirely similar to that previously used, with the single exception that the upper, instead of the lower, half of the rectangle is used, in each case, in constructing the parallelogram of forces, to determine the pressure on each joint: this is merely a matter of convenience. The student will readily identify this first line of resistance, and will see that it goes outside the arching both above and below, being farthest above the extrados at the first joint from the crown, and farthest inside of the intrados opposite the first joint from the springing. Hence we

proceed to pass a new line of resistance through the top of the first joint from the crown, and the inside of the first joint from the springing.

FIG. 284.

For this purpose we do not need to make out a new table, as it is not necessary to insert any new joints. We need only two more dimensions, i.e., the vertical depth of each of these points below the top of the crown: these depths are respectively 2.38 and 21.85.

Hence we proceed as follows:—

Let  $T$  = thrust at the crown,

$x$  = distance of its point of application below the top of the crown-joint.

1°. Take moments about the upper one of the two points, and we have

$$T(2.38 - x) = (116.18)(8.24 - 4.12) = 478.66.$$

2°. Take moments about the lower one of the two points, and we have

$$T(21.85 - x) = (607.37)(30.90 - 18.62) = 7458.50.$$

Solving these equations, we obtain

$$T = 358.9, \quad x = 1.046.$$

Hence we lay off on the crown-joint a distance 1.046 below the top of the crown-joint, and through this point draw a horizontal line, this line being the line of action of the thrust. Then, making the construction for a new line of resistance just as before, only using this new point of application of the thrust, and using for thrust 358.9, we shall obtain a new line of resistance, which passes through the desired points; and, since this line lies within the arch-ring, we therefore conclude that it is possible to draw a line of resistance within the arch-ring.

§ 267. **Examples.** — Four more examples will now be given, to be worked out by the student. The dimensions are approximately those given in some of Scheffler's examples.

EXAMPLE I. — Half-span =  $CD = 65.16$  feet, rise =  $FD = 13.85$  feet,  $AF = 5.32$  feet,  $AE = 6.40$  feet. The arcs  $CF$  and  $AG$  are concentric circular arcs. Given width of first five horizontal divisions of line  $AB$ , counting from  $A$ , each 10.66 feet; width of sixth division, 11.84 feet; of seventh, 3.68 feet. Determine the possibility of drawing a line of resistance in the arch-ring.

FIG. 285.

EXAMPLE II. — Half-span = 63.98 feet, rise =  $FD = 31.99$  feet,  $AF = CG = 5.32$  feet,  $AE = 2.13$  feet. The intrados and

extrados of this arch are seven centred ovals, both drawn from the same centres. Beginning at the springing, an arc with a radius of 21 feet is drawn, subtending  $39^\circ$ ; the curve is continued by a curve subtending  $24^\circ$ , and having a radius of 35.55 feet. From  $F$  an arc subtending  $10^\circ$  is drawn from a centre on  $FD$  produced, and with a radius of 152 feet; the curve is completed by an arc connecting the second and last.

FIG. 286.

Given horizontal width of each of first six divisions, counting from  $A$ , 10.66 feet; horizontal width of seventh division, 5.32 feet. Determine the possibility of drawing a line of resistance in the arch-ring.

FIG. 287.

EXAMPLE III.—Given span = 74.18 feet; rise = 45.83

feet; radius of intrados = 82.42 feet; radius of extrados = 91.18 feet; height of load at crown = 8.24 feet; width of each of five divisions nearest crown = 8.24 feet; width of sixth stone = 4.13 feet. Determine the possibility of drawing a line of resistance within the arch-ring.

EXAMPLE IV.—Given span = 37.07 feet; thickness of ring =  $AB = 3.08$  feet; height of load =  $BC = 82.42$  feet. Determine the possibility of drawing a line of resistance within the arch-ring.

FIG. 288.

§ 268. Criterion of Stability.—It has already been stated, that, if a line of resistance can be drawn within the arch-ring, then the true line of resistance will lie within the arch-ring.

With those who, like Scheffler, consider the material of the voussoirs incompressible, the criterion of stability of an arch is, that it should be possible to draw a line of resistance within the arch-ring.

On the other hand, Rankine would decide upon the stability of an arch by determining whether a line of resistance can be drawn within the middle third of the arch-ring.

Other limits have been adopted instead of the middle third. In some cases the only reason for deciding upon what these limits should be has been custom or precedent.

They might also be determined so that there should be no danger of exceeding the crushing-strength of the stone.

It is needless to say that the first method is incorrect; for the material of the voussoirs is never incompressible, and an arch where the true line of resistance touches the intrados or extrados could not stand, as the stone would be crushed.

Nevertheless, no example will be solved here, where we determine the possibility of drawing a line of resistance within the middle third, or other limits than the entire arch-ring, as the method of procedure is entirely similar to what we have done, the computation of the entire table being the same in all cases, the only difference occurring in the computation of the thrust and its point of application, and the consequent construction of the line of resistance. The method to be pursued is, as before, by taking moments about the points through which it is desired that the line of resistance shall pass.

§ 269. **Unsymmetrical Arrangement.** — When the arch is unsymmetrical, either in form or loading, the same criterion as to being able to pass a line of resistance within the middle third or other limits of the arch-ring will serve to determine its stability. The method of procedure differs, however, from the fact, that whereas we have heretofore found it necessary to study only the half-arch and its load, and have had the advantage of knowing, from the symmetry of arch and load, that the thrust at

the crown is horizontal, we have not that advantage here, and hence we must study the entire arch, and we must assume that the thrust at the crown may be oblique, and hence have a vertical as well as a horizontal component.

In this case it will be necessary to have three instead of two points given, in order to determine a line of resistance.

If we assume (Fig. 289) a vertical joint at the crown, and let  $P$  = vertical component of the thrust at the crown,  $A$  = horizontal component of the thrust at the crown,  $x$  = distance of point of application of thrust at the crown below upper point of crown-joint, we have thus three unknown quantities, and we shall therefore need three equations to determine them.

FIG. 289.

In this case, therefore, we must have three points of the line of resistance given, in order to determine it; and a reasoning similar to that pursued in § 263 would show that a line of resistance can always be passed through any three given points.

In performing the work, we should need to make out a table for the part of the arch on each side of the crown-joint, showing the loads, and centres of gravity of the loads, on each voussoir, and on combinations of the first two, first three, etc.; this portion of the work being entirely similar to that done in the case of arches of symmetrical form and loading, only that we require a separate table for the parts on each side of the crown-joint.

When these two tables have been worked out, we next proceed to impose the conditions of equilibrium by taking moments about each of the three points given.

Thus, suppose that (as is usually done first) we pass a line of resistance through the top of the crown-joint and the inside of each springing-joint, we then have only two unknown quantities to determine; viz.,  $P$  and  $Q$ , inasmuch as  $x$  becomes zero.

Hence we take moments about the inner edge of each of the springing-joints.

In taking moments about the inner edge of the left-hand springing-joint, we impose the conditions of equilibrium upon the forces acting on that part of the arch that lies to the left of the crown-joint. These forces are, (1°) its load and weight, which tend to cause right-handed rotation; (2°) the horizontal component of the thrust exerted *by* the right-hand portion *upon* the left-hand portion; (3°) the vertical component  $P$  of the thrust exerted *by* the right-hand portion *upon* the left-hand portion.

It is necessary to adopt some convention, in regard to the sign of  $P$ , to avoid confusion: and it will be called positive when the vertical component of the thrust exerted *by* the right-hand portion *on* the left-hand portion is upwards; when the reverse is the case, it is negative.

We next take moments about the inner edge of the right-hand springing-joint, and impose the conditions of equilibrium upon the forces acting upon the right-hand portion of the arch. In doing this, we must observe that we have for these forces, (1°) the weight and load which tend to cause left-handed rotation; (2°) the horizontal component  $Q$  of the thrust exerted *by* the left-hand portion *upon* the right-hand portion, — this acts towards the right; (3°) the vertical component  $P$  of the thrust exerted by the left-hand portion upon the right-hand portion; and this, when positive, acts downwards.

Having determined the values of  $Q$  and  $P$ , we next proceed to draw the line of resistance; and this is done in a similar way to that pursued with symmetrical arches, only that the thrust, i.e., the resultant of  $P$  and  $Q$ , is now oblique, and that it acts in opposite directions on the two sides of the crown-joint.

Having drawn this line of resistance, if we find that it passes outside of the arch-ring, we draw normals through the points where it is farthest from the arch-ring, and thus obtain three points through which to draw a line of resistance: then, taking

LEFT-HAND PORTION.

| -                      | -      | -       | 7.93  | -             | 19.578  | -                | -     | -       | -             |

RIGHT-HAND PORTION.

| Number of<br>Voussoir. | Width. | Height. | Area. | Lever<br>Arm. | Moment. | Partial<br>Sums. | Area. | Moment. | Lever<br>Arm. |
|------------------------|--------|---------|-------|---------------|---------|------------------|-------|---------|---------------|
| 1                      | 1.00   | 1.32    | 1.32  | 0.50          | 0.660   | 1                | 1.32  | 0.660   | 0.50          |
| 2                      | 1.00   | 1.48    | 1.48  | 1.50          | 2.220   | 1 + 2            | 2.80  | 2.880   | 1.03          |
| -                      | -      | -       | 2.80  | -             | 2.880   | -                | -     | -       | -             |

Now take moments about the left-hand springing inner edge, and we have

$$2.02Q + 4P = 7.93(4 - 2.47) = 12.1239.$$

Then take moments about the right-hand springing inner edge, and we have

$$0.79Q + 1.86P = 2.80(1.86 - 1.33) = 2.3240.$$

Solving these two equations gives us

$$Q = 4.602,$$

$$P = 0.707.$$

If  $R$  represent the resultant of  $P$  and  $Q$ , we have

$$R = \sqrt{P^2 + Q^2} = 4.66;$$

hence we proceed, as follows, to pass a line of resistance through the top of the crown-joint and the inner edge of each springing:—

Through the top of the crown draw a horizontal line  $BAC$ . Lay off  $Aa = 4.602$  and  $ab = 0.707$ , and draw  $Ab$ ; then  $Ab = 4.66$  represents, in direction and magnitude, the thrust at the crown. Using this thrust in the same way as we did the horizontal thrust in the case of symmetrical arches, we obtain the line of resistance  $EdAF$ , which is farthest outside of the arch at  $d$ ; hence, drawing a normal to the arch from  $d$ , we obtain  $c$ , the upper edge of the first joint from the crown. Hence we proceed to pass a new line of resistance through  $E$ ,  $c$ , and  $F$ .

To do this we must assume  $Q$ ,  $P$ , and  $x$  all unknown.

1°. Take moments about  $E$ , and we have

$$(2.02 - x)Q + 4P = 12.1239.$$

2°. Take moments about  $F$ , and we have

$$(0.79 - x)Q - 1.86P = 2.3240.$$

3°. Take moments about  $c$ , and we have

$$(0.82 - x)Q + P = (1.32)(0.50) = 0.66.$$

Solving these three equations, we obtain

$$\begin{aligned} Q &= 4.92, \\ P &= 0.64, \\ x &= 0.078. \end{aligned}$$

Hence

$$R = \sqrt{P^2 + Q^2} = 4.96.$$

Hence, if we lay off a distance 0.078 below  $A$ , we shall have the point on the crown-joint at which the thrust is applied;

and making the same kind of construction as we just made, only using this point instead of  $A$ , and these new values of  $Q$  and  $P$ , we construct the second line of resistance. The construction is omitted in order not to confuse the figure; but the line of resistance is drawn, and the student can easily make the construction for himself. It will be seen, that, in this case, this new line of resistance lies entirely within the arching.

§ 270. **General Remarks.** — Whenever there are also horizontal external forces acting upon the arch, these should be taken into account in imposing the conditions of equilibrium.

It will be noticed, that, in the preceding discussion, it has always been assumed that the load upon any one voussoir is the weight of the material directly over that voussoir. This is the assumption usually made in computing bridge arches: and it may be nearly true when the height of the load above the crown is not great; but even then it is not strictly true, and when this depth becomes great, as would be the case with an arch which supports the wall of a building, it is far from true, as the distribution of the load actually coming upon different parts of the arch must vary with, and depend upon, the bonding of the masonry, and also upon the co-efficient of friction of the material. Thus, in the case of an arch supporting a part of the wall of a building, it is probable that the only part of the load that comes upon the arch is a small triangular-shaped piece directly over the arch, and that above this the material of the wall is supported independently of the arch. This will be plain when we consider, that, were such an arch removed, the wall would remain standing, only a few of the bricks near the arch falling down; and though the number of bricks that would fall would be greater while the mortar is green, still even then only a few would drop out.

In regard to these matters, we need experiments; but thus far we have none that are reliable.

Then, again, we have arches supporting a mass of sand or gravel; and then the mutual friction of the particles on each other comes into play, and it is not true in this case that the load on any voussoir is the weight of the material directly above that voussoir. In some cases this has been accounted as a mass of water pressing normally upon the arch, but we cannot assert that such a course is correct.

On the other hand, there are cases where we know that an arch is subjected to horizontal as well as to vertical forces, and sometimes we cannot tell how great these horizontal forces are. Thus, the forms of sewers are an arch for the top and an inverted arch for the bottom; but in this case the sides of the ditch in which the sewer is laid when building it, are capable of furnishing whatever horizontal thrust is needed to force the line of resistance into the arch-ring, provided that a *horizontal thrust* is what is needed to force it in. Hence it is, that, were the attempt made to pass a line of resistance within the arch-ring of almost any successful sewer, accounting the load as the weight of the earth above it, the line would almost invariably go outside; but the earth on the sides is capable of furnishing the necessary horizontal thrust to force it inside, unless a careless workman has omitted to ram it tight, or unless some other cause has loosened it on the sides of the sewer.

If we know, in any case, the actual law of the distribution of the load, we can determine the proper form for the arch by the methods of the first part of this chapter, as was done in the case of the parabola and of the catenary. Scheffler's method is, however, the one almost always used for determining the stability of any stone arch against overturning around the joints.

Should there ever arise a case where there was danger that the resultant pressure on any joint made an angle with the joint greater than the angle of friction, this could be remedied by merely changing the inclination of the joint.

§ 271. **General Theory of the Elastic Arch.** — In the case of the iron arch, the loads upon the arch are all definitely known; and it is necessary to ascertain with certainty the stress in all parts of the structure, and to so proportion the different members as to bear with safety their respective stresses.

The general discussion of the method used in calculating such arches will now be given; the method used being practically that followed by Dr. Jacob J. Weyrauch, and explained more at length in his "*Theorie der Elastigen Bogenträger*."

This discussion is also necessary in order to prove the proposition already enunciated in § 262; viz., that "for an arch of constant cross-section, that line of resistance is approximately the true one which lies nearest to the axis of the arch-ring as determined by the method of least squares."

In this discussion the following definitions are adopted:—

- 1°. The axis of the arch is a plane curved line passing through the centres of gravity of all its normal sections.
- 2°. The plane of this axis is called the plane of the arch.
- 3°. The axial layer of the arch is a cylindrical surface perpendicular to the plane of the arch, and containing its axis.
- 4°. A section normal to the axis is called a cross-section.
- 5°. The length of the axis between two sections is called the length of arch between the sections.

The loads may be single isolated loads, or they may be distributed loads.

We shall, in this discussion, assume in the plane of the arch a pair of rectangular axes,  $OX$  and  $OY$ , positive to the right and upwards respectively.

We will, then, assuming any point on the axis of the arch before the loads are applied, call  $x, y$ , the co-ordinates of that point,  $s$  the length of axis from some arbitrary fixed point,  $\phi$  the angle made by the tangent line at that point with  $OX$ ,  $r$  the radius of curvature of the axis at that point,  $x + dx, y + dy, s + ds$ , and  $\phi + d\phi$ , the corresponding quantities for a point

FIG. 291.

very near the first before the load is applied ; also we will denote by  $\eta$  the perpendicular distance of any fibre from the axial layer, by  $S$ , the length of arc measured to that point where this fibre cuts the cross-section through  $(x, y)$ , and  $S + dS$ , the length of arc measured on this fibre to the next cross-section, so that  $ds$  will be the distance apart of the cross-sections measured on the axis, and  $dS$ , on the other fibre. All this is done before the load is applied, and is shown in Fig. 291 ; while the changes brought about by the application of the loads are denoted by  $\Delta$ 's, and shown in Fig. 292. Thus,  $x, y, s$ , and  $\phi$  become respectively  $x + \Delta x, y + \Delta y, s + \Delta s$ , and  $\phi + \Delta \phi$ .

Now, the course we are to follow in the discussion is, to imagine a cross-section dividing the arch into two parts, and to impose the conditions of equilibrium between the external forces acting on the part to one side of the section, and the forces exerted by the other part upon this part at the section. These latter forces may be reduced to the three following : —

FIG. 292.

1°. A normal thrust  $T_x$  uniformly distributed over the section, the resultant acting at the centre of gravity of the section.

2°. A shearing-force  $S_x$  at the section.

3°. A bending-couple at the section ; this comprising a stress varying uniformly from the axial layer, and amounting to a statical couple, tension below, and compressions above, the axial layer.

Moreover, (1) and (3) combined amount to a uniformly vary-

ing stress, the magnitude of whose resultant is  $T_x$ , its point of application not being at the centre of gravity of the section; this sort of composition having been already exhibited in the case of the short strut (§ 207).

Now, let  $r$  be the radius of curvature of the axial layer at the section; and we have, from Fig. 291, by similar sectors,

$$dS_\eta = dS + \eta(-d\phi) = dS - \eta d\phi. \quad (1)$$

But

$$\begin{aligned} r(-d\phi) &= ds & \therefore \frac{d\phi}{ds} &= -\frac{1}{r} \\ \therefore dS_\eta &= ds\left(1 + \frac{\eta}{r}\right) = ds\left(\frac{r + \eta}{r}\right). \end{aligned} \quad (2)$$

Now, if the loads are applied, and the changes take place that are indicated in Fig. 292, we shall have, by suitable substitutions in (1),

$$d(S_\eta + \Delta S_\eta) = d(S + \Delta S) - \eta d(\phi + \Delta \phi); \quad (3)$$

and, combining this with (1) and (2), we obtain

$$\frac{d\Delta S_\eta}{dS_\eta} = \left(\frac{d\Delta S}{ds} - \eta \frac{d\Delta \phi}{ds}\right) \frac{r}{r + \eta}. \quad (4)$$

Now, the change of length of fibre from  $dS_\eta$  to  $d(S_\eta + \Delta S_\eta)$  is due to two causes: (1) the change of temperature, (2) the stress acting on the fibre normal to the section.

Let  $\epsilon$  = co-efficient of expansion per degree temperature.

$\tau$  = difference of temperature, in degrees.

$p_\eta$  = intensity of stress along the fibre at section.

$E$  = modulus of elasticity of the material.

Then

$$\epsilon\tau - \frac{p_\eta}{E} = \frac{d\Delta S_\eta}{dS_\eta} = \left(\frac{d\Delta S}{ds} - \eta \frac{d\Delta \phi}{ds}\right) \frac{r}{r + \eta}. \quad (5)$$

Hence, solving for  $p_\eta$ , we have

$$p_\eta = E\left(\eta \frac{d\Delta \phi}{ds} - \frac{d\Delta S}{ds}\right) \frac{r}{r + \eta} + E\epsilon\tau, \quad (6)$$

this being the expression for the stress per square inch on the fibre whose distance is  $\eta$  from the axial layer.

Hence we shall have, by summation, if elementary area =  $dA$ ,

$$T_x = \Sigma p_\eta dA = E \left[ \frac{d\Delta\phi}{ds} \Sigma \frac{r\eta dA}{r + \eta} - \frac{d\Delta s}{ds} \Sigma \frac{rdA}{r + \eta} + \epsilon \Sigma r dA \right]; \quad (7)$$

and for the moment  $M_x$  we have, by taking moments about the neutral axis of the section (i.e., horizontal line through its centre of gravity),

$$M_x = \Sigma p_\eta \eta dA = E \left[ \frac{d\Delta\phi}{ds} \Sigma \frac{r\eta^2 dA}{r + \eta} - \frac{d\Delta s}{ds} \Sigma \frac{r\eta dA}{r + \eta} + \epsilon \Sigma r\eta dA \right]. \quad (8)$$

Let  $\Sigma dA = A$ ,  $\Sigma \frac{\eta^2 dA}{r + \eta} = \Omega$ , and observe that  $\Sigma \eta dA = 0$ , since the axis passes through the centre of gravity of the section, and we have

$$\Sigma \frac{r\eta dA}{r + \eta} = \Sigma \eta dA - \Sigma \frac{\eta^2 dA}{r + \eta} = -\Omega,$$

$$\Sigma \frac{rdA}{r + \eta} = \Sigma dA - \frac{1}{r} \Sigma \eta dA + \frac{1}{r} \Sigma \frac{\eta^2 dA}{r + \eta} = A + \frac{\Omega}{r}$$

Making these substitutions, we have

$$\frac{T_x}{E} = - \left( \frac{d\Delta\phi}{ds} + \frac{1}{r} \frac{d\Delta s}{ds} \right) \frac{\Omega}{r} - \left( \frac{d\Delta s}{ds} - \epsilon \right) A,$$

$$\frac{M_x}{E} = \left( r \frac{d\Delta\phi}{ds} + \frac{d\Delta s}{ds} \right) \frac{\Omega}{r}$$

Hence, solving for  $\frac{d\Delta s}{ds}$  and  $\frac{d\Delta\phi}{ds}$ , we have

$$\frac{d\Delta s}{ds} = - \left( T_x + \frac{M_x}{r} \frac{1}{EA} \right) + \epsilon = Y, \quad (9)$$

$$\frac{d\Delta\phi}{ds} = \left( T_x + \frac{M_x}{r} \right) \frac{1}{EA r} + \frac{M_x}{E\Omega} - \frac{\epsilon}{r} = X. \quad (10)$$

Now, from Fig. 292, we have

$$d(x + \Delta x) = d(s + \Delta s) \cos(\phi + \Delta\phi),$$

$$d(y + \Delta y) = d(s + \Delta s) \sin(\phi + \Delta\phi);$$

but, if we write  $\cos \Delta\phi = 1$ , and  $\sin \Delta\phi = \Delta\phi$ ,

$$\cos(\phi + \Delta\phi) = \cos \phi - \Delta\phi \sin \phi = \frac{dx}{ds} - \Delta\phi \frac{dy}{ds},$$

$$\sin(\phi + \Delta\phi) = \sin \phi + \Delta\phi \cos \phi = \frac{dy}{ds} + \Delta\phi \frac{dx}{ds}.$$

Hence

$$d\Delta x = -\Delta\phi dy + \frac{d\Delta s}{ds} dx - \left( \frac{d\Delta s}{ds} dy \Delta\phi \right),$$

$$d\Delta y = +\Delta\phi dx + \frac{d\Delta s}{ds} dy + \left( \frac{d\Delta s}{ds} dx \Delta\phi \right);$$

or, omitting the last terms, and integrating,

$$\Delta x = -\int \Delta\phi dy + \int Y ds, \quad (11)$$

$$\Delta y = \int \Delta\phi dx + \int Y dy; \quad (12)$$

and, integrating (9) and (10),

$$\Delta s = \int Y ds, \quad (13)$$

$$\Delta\phi = \int X ds. \quad (14)$$

In these four equations we have

$\Delta x$  = horizontal deflection due to the loads,

$\Delta y$  = vertical deflection due to the loads,

$\Delta s$  = change of length of arc due to the loads,

$\Delta\phi$  = change of slope due to the loads.

If, now, we write

$$M_1 = \frac{M_x}{E\Omega} + \frac{M_x}{EA r^2} + \frac{T_x}{EA r},$$

$$P_1 = \frac{M_x}{EA r} + \frac{T_x}{EA},$$

we shall have

$$X = M_1 - \frac{\epsilon \tau}{r}, \quad Y = -P_1 - \epsilon \tau;$$

and hence (11) to (14) become

$$\Delta x = -\iint M_1 ds dy - \int P_1 dx + \int \int \frac{\epsilon \tau}{r} ds dy - \int \epsilon \tau dx, \quad (15)$$

$$\Delta y = \iint M_1 ds dx - \int P_1 dy - \int \int \frac{\epsilon \tau}{r} ds dy - \int \epsilon \tau dy, \quad (16)$$

$$\Delta s = - \int P_1 ds - \int \epsilon \tau ds, \quad (17)$$

$$\Delta \phi = \int M_1 ds - \int \frac{\epsilon \tau}{r} ds. \quad (18)$$

If we neglect the effect of temperature, they become

$$\Delta x = -\iint M_1 ds dy - \int P_1 dx, \quad (19)$$

$$\Delta y = \iint M_1 ds dx - \int P_1 dy, \quad (20)$$

$$\Delta s = - \int P_1 ds, \quad (21)$$

$$\Delta \phi = \int M_1 ds. \quad (22)$$

If, on the other hand, we do not neglect the effect of temperature, but omit all terms containing  $\frac{1}{r}$  in the values of  $X$  and  $Y$ , which would be more nearly correct the larger the value of  $r$ , i.e., the flatter the arch, we should obtain

$$\Delta x = - \int \int \frac{M_x}{E\Omega} ds dy - \int \frac{T_x}{EA} dx - \int \epsilon \tau dx, \quad (23)$$

$$\Delta y = \int \int \frac{M_x}{E\Omega} ds dx - \int \frac{T_x}{EA} dy - \int \epsilon \tau dy, \quad (24)$$

$$\Delta s = - \int \frac{T_x}{EA} ds - \int \epsilon \tau ds, \quad (25)$$

$$\Delta \phi = \int \frac{M_x}{E\Omega} ds. \quad (26)$$

Moreover, if we put the moment of inertia  $I$  for  $\Omega$ , which will cause but little error, we derive

$$\Delta x = - \int \int \frac{M_x}{EI} ds dy - \int \frac{T_x}{EA} dx - \int \epsilon dx, \quad (27)$$

$$\Delta y = \int \int \frac{M_x}{EI} ds dx - \int \frac{T_x}{EA} dy - \int \epsilon dy, \quad (28)$$

$$\Delta s = - \int \frac{T_x}{EA} ds - \int \epsilon ds, \quad (29)$$

$$\Delta \phi = \int \frac{M_x}{EI} ds. \quad (30)$$

§ 272. Manner of using the Fundamental Equations to Determine the Stresses in an Iron Arch. — In order to be able to determine the stresses in all the members of an iron arch with any given loading, we need to determine the three quantities  $T_x$ ,  $S_x$ , and  $M_x$  for each section.

Now, if we let  $R_x$  represent the thrust at the section, we shall have

$$R_x = \sqrt{T_x^2 + S_x^2}; \quad (1)$$

and, if we let  $H_x$  and  $V_x$  represent the horizontal and vertical components of  $R_x$  respectively, we have that we need to determine the three quantities  $H_x$ ,  $V_x$ , and  $M_x$  for each section.

If we suppose the arch to be subjected to vertical loads only, we shall have, if we let

$H$  = horizontal component of thrust at all points,

$V$  = vertical component of left-hand support,

$V_i$  = vertical component of right-hand support,

$M$  = bending-moment at left-hand support,

$M'$  = bending-moment at right-hand support.

Assume origin of co-ordinates at left-hand support, and  $x$  + to the right, and  $y$  + upwards, and impose the conditions of equilibrium upon the forces acting on the part of the arch

between the section and the left-hand support ; then we have, if  $W$  is any one load, and  $a$  the  $x$  of its point of application,

$$H_x = H, \quad (2)$$

$$V_x = V - \sum_0^x W, \quad (3)$$

$$M_x = M + Vx - Hy - \sum_0^x W(x - a). \quad (4)$$

Hence it is plain that the three quantities which we need to determine are  $H$ ,  $V$ , and  $M$ .

Now these are also the three unknown quantities which will, by suitable reductions, become the three unknown constant quantities in equations (27) to (30). The determination of these three quantities requires three conditions ; what these conditions are depends upon the manner of building the arch, as will be seen from the following three special cases :—

CASE I. — Let the arch be jointed at three points, viz., the two supports, and one other point whose co-ordinates are  $x = x_1$  and  $y = y_1$ . Then we know, that, for all points where there is a hinge, there can be no bending-moment. Hence

$$M = 0, \quad M' = 0, \quad \text{and} \quad M_{x_1} = 0,$$

which are the three required conditions ; and, if these be imposed, it is easy to obtain  $H_x$ ,  $V_x$ , and  $M_x$  for every section.

CASE II. — Let the arch be jointed only at the ends. Then  $M = M' = 0$  gives us two conditions : and for the third we have  $\Delta l = 0$  ; i.e., if we put  $l$  for  $x$  in equation (15) or (27), § 271, after having made the integrations, we have the third equation, as this expresses simply the condition that the supports remain at the same horizontal distance apart after the load is put on as before. With these three conditions we can determine  $H_x$ ,  $V_x$ , and  $M_x$  for all sections.

CASE III. — Let the arch be fixed in direction at the ends. We must now have three conditions. These will be as follows :—

1°.  $\Delta l = 0$  ; i.e., the supports remain at the same horizontal distance apart after the load is applied as before.

2°.  $\Delta h = 0$ ; ( $h$  being the difference of level of the supports); i.e., the supports remain at the same vertical distance apart after as before the load is applied.

3°.  $\Delta \phi_1 = 0$ ; i.e., the tangents at the ends make the same angle with each other after as before the load is applied.

The value of  $\Delta l$  is obtained by integrating (15) or (27), § 271, and then substituting  $l$  for  $x$ .

The value of  $\Delta h$  is obtained by integrating (16) or (28), § 271, and then substituting  $l$  for  $x$ , or  $h$  for  $y$ .

The value of  $\Delta \phi_1$  is obtained by integrating (18) or (30), § 271, and then substituting  $l$  for  $x$ , or  $h$  for  $y$ .

In this case we often find it convenient to use these equations in a simpler form. Thus, suppose we adopt the case where we neglect the effect of temperature (i.e., equations (19), (20), and (22) of § 271), by making one integration they become

$$\Delta x = -\int M_1 y ds - \int P_1 dx, \quad (5)$$

$$\Delta y = +\int M_1 x ds - \int P_1 dy, \quad (6)$$

$$\Delta \phi = \int M_1 ds; \quad (7)$$

these being more convenient to use.

For very flat arches,  $P_1$  becomes very small: and then the equations become

$$\Delta x = -\int M_1 y ds, \quad (8)$$

$$\Delta y = +\int M_1 x ds, \quad (9)$$

$$\Delta \phi = \int M_1 ds; \quad (10)$$

and these, if all terms containing  $\frac{1}{r}$  be omitted, become

$$\Delta x = -\int \frac{M_x}{EI} y ds, \quad (11)$$

$$\Delta y = +\int \frac{M_x}{EI} x ds, \quad (12)$$

$$\Delta \phi = \int \frac{M_x}{EI} ds. \quad (13)$$

## EXAMPLES.

1. Given a semicircular arch jointed at each springing-joint and at the crown, radius  $r$ . Trace out the effect of a single load  $W$  acting upon it at the extremity of a radius making  $45^\circ$  with the horizontal.

*Solution.*

The presence of three joints gives us the bending-moments at each of these joints equal to zero, the co-ordinates of these joints being respectively  $(0, 0)$ ,  $(r, r)$ , and  $(2r, 0)$ .

Hence, using equation (4), we obtain

$$1^\circ. M = 0,$$

$$2^\circ. Vr - Hr - W(0.70711r) = 0,$$

$$3^\circ. V(2r) - W(1.70711r) = 0.$$

Solving, we have, therefore,

$$V = 0.85355 W = \text{left-hand supporting-force,}$$

and

$$H = 0.14645 W = \text{horizontal component of thrust.}$$

Hence  $V_1 = 0.14645 W = \text{right-hand supporting-force.}$

Hence, for a section whose co-ordinates are  $(x, y)$ ,

$$x < 0.29289r, \quad V_x = 0.85355 W;$$

$$x > 0.29289r, \quad V_x = -0.14645 W.$$

Hence equation (1) gives, for

$$x < 0.29289r, \quad R_x = W\sqrt{(0.85355)^2 + (0.14645)^2} \\ = 0.86602 W,$$

$$x > 0.29289r, \quad R_x = W\sqrt{(0.14645)^2 + (0.14645)^2} \\ = 0.20711 W.$$

Now, the angle made by  $R_x$  with the horizontal is, for

$$x < 0.29289r, \quad \alpha_1 = \tan^{-1}\left(\frac{0.85355}{0.14645}\right) = 80^\circ 15' 51'',$$

$$x > 0.29289r, \quad \alpha_1 = \tan^{-1}\left(\frac{0.14645}{0.14645}\right) = 45^\circ.$$

Knowing, now, the angle made by  $R_x$  with the horizontal, we can find, for the point  $(x, y)$ , the angle made by a tangent to the circle with the horizon, or  $\alpha_2 = \tan^{-1}\left(\frac{r-x}{y}\right)$ . Then resolve  $R_x$  into two components, respectively tangent to the arch and normal to it at the point  $x, y$ , and the tangential component is the direct thrust  $T_x$ , while the normal is the shearing-force  $S_x$ .

Then, for the bending moment, we have, from (4),

$$x < 0.29289r, \quad M_x = 0.85355 Wx - 0.14645 Wy;$$

$$x > 0.29289r, \quad M_x = 0.85355 Wx - 0.14645 Wy - W(x - 0.29289r).$$

Hence we determine the direct thrust, the shearing-force, and the bending-moment at any section, and can hence obtain the stresses at all points.

2. Given the same arch with a load  $W$  distributed uniformly over the circular arc, find stresses at all points.

3. Given the same arch jointed only at the two springing-points, find stresses at all points.

§ 273. **Position of True Line of Resistance in a Stone Arch.** — The proof will now be given of the proposition already referred to in regard to the position of the true line of resistance; viz., —

“For an arch of constant section, that line of resistance is approximately the true one which lies nearest to the axis of the arch-ring, as determined by the method of least squares.”

PROOF. — If we denote by  $y$  the ordinate of the axis of the arch for an abscissa  $x$ , and by  $\mu$  that of the line of resistance for the same abscissa, then  $\mu - y$  is the vertical distance between the two curves for abscissa  $x$ . Now, the condition that the line of resistance should be as near the arch-ring as possible, is, that the sum of the  $(\mu - y)^2$  shall be a minimum, or

$$\int (\mu - y)^2 ds = \text{minimum.} \quad (1)$$

But  $(x, \mu)$  are the co-ordinates of the point of application of the

actual thrust, and hence  $(\mu - y)$  is the distance of the point at which the resultant thrust acts from the centre of gravity of the section. Hence we have

$$\mu - y = \frac{M_x}{H}.$$

Hence (1) becomes

$$\int \left( \frac{M_x}{H} \right)^2 ds = \text{minimum.} \quad (2)$$

But  $H$  is constant for the same line of resistance, though it varies for different lines: hence we can place  $H$  outside of the integral sign. Hence we may write

$$u = \frac{1}{H^2} \int M_x^2 ds = \text{minimum.} \quad (3)$$

Now, from (4), § 272, we have

$$M_x = M + Vx - Hy - \Sigma_0^x W(x - a) = \phi(M, V, H);$$

$M$ ,  $V$ , and  $H$  being constants for the same line of resistance, but varying for different lines. Hence, by differentiating (3), we have

$$\frac{du}{dM} = \frac{du}{dM_x} \frac{dM_x}{dM} = \frac{2}{H^2} \int M_x ds = 0 \quad \therefore \int M_x ds = 0, \quad (4)$$

$$\frac{du}{dV} = \frac{du}{dM_x} \frac{dM_x}{dV} = \frac{2}{H^2} \int M_x x ds = 0 \quad \therefore \int M_x x ds = 0 \quad (5)$$

$$\begin{aligned} \frac{du}{dH} &= \frac{du}{dM_x} \frac{dM_x}{dH} = -2H^{-3} \int M_x^2 ds + 2H^{-2} \int M_x y ds \\ &= -H^{-1} \left\{ \frac{2}{H^2} \int M_x^2 ds + 2 \frac{1}{H} \int M_x y ds \right\} = 0. \end{aligned}$$

But the first term must be very small: hence we may write approximately,

$$\int M_x y ds = 0. \quad (6)$$

Now, the three expressions (4), (5), and (6) are identical with (11), (12), and (13) of § 272; and the conditions that these shall be zero are, as will be seen by referring to § 272, Case III., the

conditions that hold in the case of an arch fixed in direction at the ends. Hence it follows that the condition that the line of resistance shall fall as near the centre of the arch as possible is the condition which, in an elastic arch fixed in direction at the ends, gives us its true position. Hence it would seem that the most probable position for the true line of resistance is the nearest possible to the axis of the arch.

This is the conclusion reached by Winkler; and a more detailed discussion of the matter is to be found in an article by Professor Swain in "Van Nostrand's" for October, 1880.

§ 274. **Domes.**—The method to be used for determining the stability of a dome differs essentially from that used in the case of an arch, for there is no thrust at the crown in a dome. Indeed, the most general case is that of the dome open at the top: we will, therefore, consider this case first in studying the action of the forces required to preserve equilibrium.

Fig. 243 shows a meridional section of an open dome. Suppose that this dome had been entirely built, except the upper ring-course of stones, represented by *LKGH*. Then, suppose that one of the stones only of this course were placed in position without any auxiliary support, its own weight would evidently overturn it, since the line *ab*, along which the weight acts, does not cut the joint; but, if the whole ring-course is put in place, the stones keep each other in position. The way in which this is accomplished is as follows: they press laterally against each other; and the resultant of the

FIG. 243.

pressures exerted upon the two lateral faces of any one stone by the other stones of the course is a horizontal radial force, which, combined with the weight of the stone, gives, as the resultant of the two, a force which cuts the joint between  $G$  and  $H$ . Moreover, sufficient pressure will be developed to accomplish this result, as a failure to reach the result will only increase the pressure upon the lateral faces.

Moreover, if, when sufficient pressure has been developed to bring the resultant of the weight of the stone and the above-described horizontal radial force within the joint, it should make an angle with the normal to the joint greater than the angle of friction, the tendency of the stone to slide will increase the lateral pressure, and this in turn will increase the outward horizontal force till the angle made by the resultant with the normal to the joint is no greater than the angle of friction of the material of the voussoirs.

This will be made plain by reference to the figure (Fig. 243), where  $ab$  represents the weight of the stone  $HLKG$ , and where  $O\beta$  is perpendicular to  $HG$  and  $O\gamma$  is drawn so that  $\gamma O\delta = \phi$ , the angle of friction. Now, since  $ab$  produced passes outside of  $HG$ , horizontal thrust must be developed. And, moreover, were only sufficient horizontal thrust furnished to make the resultant cut  $HG$  at  $G$ , the angle between this resultant and the normal to the joint would be greater than  $\phi$ ; therefore we proceed as follows: assuming the horizontal thrust to act through  $L$ , the upper edge of the stone, we lay off from  $b$ , the intersection of the horizontal through  $L$  with a vertical line drawn through the centre of gravity of the stone, the weight  $ab$  to scale, then from  $b$  draw  $bc$  parallel to  $O\gamma$ , and draw through  $a$  a horizontal line to meet  $bc$ . Then will  $ac$  be the horizontal force that will be furnished by the other stones of the course to keep this stone in place; and the pressure upon joint  $HG$  is  $bc$ , and acts at the intersection of  $bc$  and  $HG$ .

Now prolong  $bc$  to meet the vertical drawn through the

centre of gravity of the next stone,  $HGFE$ , at  $d$ . Combine it with the weight of this stone; this is done by laying off  $de = bc$ , and from  $e$  drawing  $ef$  vertical, and equal to the weight of  $FHGE$ . The resultant  $fd$  makes an angle with the normal to  $FE$  greater than  $\phi$ : hence draw  $O\delta$  perpendicular to  $FE$  and  $O\epsilon$ , so that  $\epsilon O\delta = \phi$ ; then from  $g$ , the intersection of  $df$  with a horizontal line through  $H$ , the top of  $FHGE$ , lay off  $gs = df$ , through  $g$  draw  $gh$  parallel to  $O\epsilon$ , and through  $s$  draw  $sh$  horizontal. Then is  $sh$  the horizontal thrust that will be furnished at  $H$  to keep the stone  $HGEF$  in place; and this is the pressure upon joint  $FE$ , and acts at the intersection of  $FE$  with  $hg$ .

Next, prolong  $hg$  to meet the vertical through the centre of gravity of stone  $FEDC$  at  $k$ ; lay off  $kl = gh$ , and from  $l$  lay off  $lm =$  weight of stone  $FEDC$ ; draw  $km$ , which cuts the joint within the joint itself, and needs no horizontal thrust to bring it inside; hence  $mk$  is the pressure on joint  $DC$ .

Then draw  $mk$  to meet the vertical through the centre of gravity of  $ABCD$  at  $n$ , and lay off  $no = km$ ; draw  $op =$  weight of  $ABCD$ , and draw  $pn$ , which will be the pressure on the joint  $BA$ .

It is necessary, for stability, that all these forces should cut the joint inside of the joint if the stones are reckoned incompressible; or we may adopt the middle third, or other limits, as our criterion of stability.

As long as it is outward thrust that is required to produce stability, it is possible to furnish it; but, if we should reach a joint where inward thrust would be required, this could not be furnished, and the dome would be unstable. Moreover, the resultant pressure on the springing gives us the pressure exerted upon the support of the dome; and it must not cut any joint of the support outside of that joint, as otherwise the support would not stand.

In determining the numerical value and direction of this pressure on the support, we may either construct it graphically,

or we may compute it as follows: (1°) Compound all the vertical forces, i.e., the weights, and find the magnitude and line of action of the resultant of these. (2°) Compound all the horizontal forces, and find the magnitude and line of action of their resultant (in this case the horizontal forces are two; viz,  $ac$  applied at  $L$ , and  $sh$  applied at  $H$ ); then compound these two resultants. The graphical and analytical method should check if no mistake has been made in the work.

In the above calculation, it has been assumed that the figure represents the portion of a dome included between two meridional planes.

If we desire to ascertain the pressure exerted upon the lateral face of the stone by its neighbors in the same ring-course, we only need to know the angle made by the two meridional planes containing the lateral faces of the stone in question, then resolve the horizontal thrust upon that stone into two equal components, which make with each other an angle equal to the supplement of the angle of the planes; i.e., resolve the outward horizontal thrust into two components normal to the lateral faces.

In regard to the assumption that the outward thrust acts at the top of the stone, it should be said that this is Scheffler's custom, his reason being that less thrust will be required if he assumes it at the top than if he assumes it nearer the middle. The true position of this thrust is probably much nearer the middle of the stone.

An example will next be solved, giving Scheffler's method of working.

EXAMPLE. — Given the dome shown in the figure, surmounted by a lantern at the top; determine whether it is stable, and what should be the thickness of the support in order that the resultant pressure may not pass outside any joint of the pier.

The dimensions are as follows :—

Diameter of outer vertical circle = 20 feet.

Diameter of inner vertical circle = 18 feet.

Angle made by springing-radius with vertical =  $75^\circ$  = angle  $AOB$ .

The inner edge of the upper voussoir subtends  $18^\circ$  on the lower circle; the width of the load of the lantern is 0.6; the voussoirs below that, each subtend  $18^\circ$ .

Assume 36 stones in a horizontal course. The width of the lowest will, then, be 1.51; the width of the others are determined from their lever arms.

Given height of pier = 8 feet.

Height of the centre of the sphere above base of pier =  $8' - 10 \sin 15^\circ = 5.41'$ .

The figure may be taken to represent the portion of the dome included between two vertical planes passing through the axis of the dome: hence it shows one vertical series of stones.

We first construct a table giving the weights of the different voussoirs with any superincumbent load, their centres of gravity, and the moments of their weights about an axis passing through  $O$ , and perpendicular to the central plane of the portion shown; and we so choose our unit of weight that the volumes of the

FIG. 294.

voussoirs shall represent their weights. The work is arranged as follows :—

| ELEMENTARY FORCES. |                       |             |          |             |         | HORIZONTAL FORCES.  |             |         |
|--------------------|-----------------------|-------------|----------|-------------|---------|---------------------|-------------|---------|
| (1)                | (2)                   | (3)         | (4)      | (5)         | (6)     | (7)                 | (8)         | (9)     |
| No. of Voussoir.   | Area of Lateral Face. | Thick-ness. | Product. | Lever Arms. | Moment. | Horiz-ontal Forces. | Lever Arms. | Moment. |
| 1                  | 0.6 × 6.680           | 0.53        | 2.124    | 3.07        | 6.521   | 1.74                | 9.60        | 16.104  |
| 2                  | 2.985                 | 0.74        | 2.209    | 4.75        | 10.493  | 1.26                | 9.33        | 11.756  |
| 3                  | 2.985                 | 1.23        | 3.672    | 7.05        | 25.888  | 1.32                | 7.78        | 10.273  |
| 4                  | 2.985                 | 1.51        | 4.507    | 8.68        | 39.121  | —                   | —           | —       |
| —                  | —                     | —           | 12.512   | —           | 82.023  | 4.32                | —           | 38.730  |

Column (1) contains the numbers of the voussoirs, counting from the top.

Column (2) contains the areas of the lateral faces of the stones shown in the figure. For the three lower stones, the area of a ring subtending 18° at the centre, and of the dimensions given, is calculated. For the first, the height is 6.68 and the width 0.6.

Column (3) contains the thicknesses of the voussoirs; i.e., the length of arc between their two lateral faces measured on a horizontal circle through the centre of gravity of the voussoir, which is here taken at the middle point of the arc subtended by this voussoir on its middle vertical circle, i.e., one which has a radius 9.5 feet.

Hence, the thickness of the lower stone being 1.51 feet, that of the others will be

$$(1.51) \frac{3.07}{8.68} = 0.53, \quad (1.51) \frac{4.25}{8.68} = 0.74,$$

$$(1.51) \frac{7.05}{8.68} = 1.23.$$

Column (4) gives the weights of the voussoirs and their loads: it is obtained by multiplying together the numbers in columns (2) and (3).

Column (5) gives the distances of the centres of gravity of the different voussoirs from the axis of the dome: it may be determined graphically or by calculation.

Column (6) gives the moments of the weights about a horizontal axis through *O* perpendicular to the central plane of this series of voussoirs. The graphical construction for determining the horizontal thrusts required is next made, and the results are recorded in column (7). It will be seen that no thrust is required on voussoir No. 4.

Column (8) contains the lever arms of these forces about the same axis.

Column (9) contains their moments about the same axis.

The construction thus far has shown no case where horizontal tension instead of horizontal thrust is required to cause the thrust on any joint to pass within the joint: hence thus far the dome is stable; and the question comes next as to what should be the width of the pier in order that the line of resistance, if continued down, may remain within it.

For this purpose we proceed as follows:—

Let  $t$  = thickness required.

Let breadth be equal to that of the lowest voussoir.

Height = 8 feet.

Take moments about the outer edge of the base of the pier.

We shall then have, —

1°. Moment of vertical load on dome, and of weight of dome sector about inner edge of springing, =

$$(12.512)(8.68 - 6.56) = 26.52.$$

2°. Moment of same about outer edge of springing of pier =

$$26.52 + (12.512)t.$$

3°. Moment of horizontal forces about the same axis =

$$38.730 + (4.32)(5.41) = 62.101.$$

4°. Moment of weight of pier about outer edge =

$$\{8(1.51)t\}\frac{1}{2}t = 6.04t^2.$$

Hence we have

$$6.04t^2 + 12.51t + 26.52 = 62.101$$

$$\therefore t^2 + 2.07t = 5.89 \quad \therefore t = 1.60 \text{ feet.}$$

This is the thickness required in order that the line of resistance may remain within the lower joint.

If, on the other hand, while pursuing the same method with the dome itself, we require that the line of resistance shall remain within the middle third of the pier, we take moments about a point in the springing of the pier at a distance  $\frac{2}{3}t$  from its inner edge, we should then have

$$\frac{4}{3}t^2 + \frac{4}{3}(2.07)t = 5.89$$

$$\therefore t^2 + 2.07t = 8.84 \quad \therefore t = 2.10 \text{ feet.}$$

On the other hand, we could proceed in a similar way to the above, if we desired to keep the line of resistance in the dome within the middle third, by merely assuming the horizontal thrusts to act at two-thirds the thickness of a joint from the lower edge, and using a point two-thirds the thickness from the top, instead of the lower edge, as the lower limiting-point for the pressure to pass through.

This will not be done here, however.

EXAMPLE. — As an example, St. Peter's dome will be given, with the dimensions as given by Scheffler reduced to English measures. The dome consists in its upper part, as will be evident from the figure, of two domes; the lantern resting on

the two is assumed to have one-third of its weight resting on the upper, and two-thirds on the lower dome.

Diameter of dome = diameter at the base = 144 feet.

Up to a point 28.48 feet above the point *C* it is formed of a single dome 11.84 feet thick. In its upper part, on the other hand, it is composed of two domes whose normal distance apart is 5.15 feet; the exterior having a thickness of 2.56 feet, and the inner of 4.13 feet at the top and 5.15 feet at the springing. At the top of these two domes is an opening 12.24 feet radius, surmounted by a cylindrical lantern. The magnitude of the load of the lantern on the dome is represented on the figure by 1.82 feet width and 56.66 feet height.

Height of the entablature  $ABCD = 23.69$ .

Width of  $ABCD$  normal to plane of paper = 1.02 feet.

Thickness of  $ABCD = 10.30$  feet.

Divide the exterior dome into nine parts, the interior into eight of a uniform circumferential width of 10.08 feet, except the first, which has a width of only 1.82 feet.

Determine whether this thickness of  $ABCD$  is sufficient to keep the line of resistance within joint  $AB$ .

FIG. 295.

## CHAPTER X.

## THEORY OF ELASTICITY, AND APPLICATIONS.

§ 275. **Strains.**—When a body is subjected to the action of external forces, and in consequence of this undergoes a change of form, it will be found that lines drawn within the body are changed, by the action of these external forces, in length, in direction, or in both; and the entire change of form of the body may be correctly described by describing a sufficient number of these changes.

If we join two points,  $A$  and  $B$ , of a body before the external forces are applied, and find, that, after the application of the external forces, the line joining the same two points of the body has undergone a change of length  $\Delta(AB)$ , then is the limit of the ratio  $\frac{\Delta(AB)}{AB}$ , as  $AB$  approaches zero, called the *strain* of the body at the point  $A$  in the direction  $AB$ .

If  $AB + \Delta(AB) > AB$ , the strain is one of tension; whereas, if  $AB + \Delta(AB) < AB$ , the strain is one of compression.

In order to study the changes of form of the body, let us assume a point  $O$  within the body when there are no external forces acting, and let us draw through this point three rectangular axes,  $OX$ ,  $OY$ , and  $OZ$ , and assume a small rectangular parallelepipedical particle whose three edges are  $OA$ ,  $OB$ , and

$OC$ , and let us examine the form of this particle after the loads are applied; it will be found that the edges  $OA$ ,  $OB$ , and  $OC$  will be of different lengths from what they were before, and that the angles  $AOB$ ,  $AOC$ , and  $BOC$  will no longer be right angles, but will differ slightly from  $90^\circ$ . Let the paralleliped  $oabc-gdef$  represent the form and dimensions of the particles after the external forces are applied. Then we shall have, if  $\epsilon_x$ ,  $\epsilon_y$ , and  $\epsilon_z$  represent the strains in the directions  $OX$ ,  $OY$ , and  $OZ$  respectively, that

FIG. 296.

$$\epsilon_x = \text{limit of } \frac{oa - OA}{OA} \text{ as } OA \text{ approaches zero,}$$

$$\epsilon_y = \text{limit of } \frac{ob - OB}{OB} \text{ as } OB \text{ approaches zero,}$$

$$\epsilon_z = \text{limit of } \frac{oc - OC}{OC} \text{ as } OC \text{ approaches zero.}$$

In the figure,  $\epsilon_x$  and  $\epsilon_z$  are tensile strains, and  $\epsilon_y$  is a compressive strain.

But these strains do not represent completely the distortion of the particle; for the plane  $CEGD$  has slid by the plane  $OABF$  through the distance  $oc_1$ , the distance apart of these planes being  $OC$ , and the plane halfway between the two has slid just half as far, so that the amount of shearing, or the *shearing-strain* of planes parallel to  $XOY$  in the direction  $OX$ , may be represented by  $\frac{oc_1}{OC} = \frac{oc_1}{cc_1}$  nearly, or the distortion divided by the

distance apart of these planes. This, moreover, is the tangent of the angle  $occ_1$ , or the tangent of the angle by which  $aoc$  differs from a right angle.

If, now, we let

$\gamma_{xx}$  = shearing-strain in a plane perpendicular to  $OZ$  in the direction  $OX$ ,

$\gamma_{yy}$  = shearing-strain in a plane perpendicular to  $OZ$  in the direction  $OY$ ,

$\gamma_{yx}$  = shearing-strain in a plane perpendicular to  $OY$  in the direction  $OX$ ,

$\gamma_{yz}$  = shearing-strain in a plane perpendicular to  $OY$  in the direction  $OZ$ ,

$\gamma_{zx}$  = shearing-strain in a plane perpendicular to  $OX$  in the direction  $OZ$ ,

$\gamma_{xy}$  = shearing-strain in a plane perpendicular to  $OX$  in the direction  $OY$ ,

and let  $boc = \frac{\pi}{2} - \phi$ ,  $aoc = \frac{\pi}{2} - \psi$ ,  $aob = \frac{\pi}{2} - \chi$ , then we shall have

$$\begin{aligned}\gamma_{xx} &= \frac{oc_1}{cc_1} = \tan \psi, & \gamma_{yz} &= \tan \phi, \\ \gamma_{yy} &= \tan \phi, & \gamma_{zx} &= \tan \psi, \\ \gamma_{yx} &= \tan \chi, & \gamma_{xy} &= \tan \chi.\end{aligned}$$

We thus have

$$\begin{aligned}\gamma_{xy} &= \gamma_{yz} = \tan \phi, \\ \gamma_{xz} &= \gamma_{xx} = \tan \psi, \\ \gamma_{xy} &= \gamma_{yx} = \tan \chi.\end{aligned}$$

three very important equations.

We thus have to determine six strains, in order to define completely the state of strain in a body at a given point; viz., if we assume three rectangular axes, we must know  $\epsilon_x, \epsilon_y, \epsilon_z$ ,  $\gamma_{xy} = \gamma_{yz}$ ,  $\gamma_{xz} = \gamma_{xx}$ ,  $\gamma_{xy} = \gamma_{yx}$ , three normal and three tangential strains.

§ 276. **Strains in Terms of Distortions.**— Let us assume a rectangular parallelopipedical particle, the co-ordinates of one corner of which are  $x, y, z$ , and of the other,  $x + dx, y + dy, z + dz$ ; this being the case before the load is applied.

Let the effect of the load be to change  $x, y, z$ , respectively, into  $x + \xi, y + \eta, z + \zeta$ , and to change  $x + dx, y + dy, z + dz$ , into  $(x + \xi) + (dx + d\xi), (y + \eta) + (dy + d\eta), (z + \zeta) + (dz + d\zeta)$ . Then are  $dx, dy, dz$ , the edges of the particle before the load is applied.

Then, from what has preceded, we shall have

$$\epsilon_x = \frac{d\xi}{dx}, \quad \epsilon_y = \frac{d\eta}{dy}, \quad \epsilon_z = \frac{d\zeta}{dz};$$

$$\gamma_{xy} = \gamma_{yx} = \frac{d\xi}{dy} + \frac{d\eta}{dx}, \quad \gamma_{xz} = \gamma_{zx} = \frac{d\xi}{dz} + \frac{d\zeta}{dx}, \quad \gamma_{yz} = \gamma_{zy} = \frac{d\eta}{dz} + \frac{d\zeta}{dy}.$$

The first three will be evident at once. As to the last three, if the student will construct the figure indicated, he will see that

$$\frac{d\xi}{dy} + \frac{d\eta}{dx} = \tan \chi, \quad \frac{d\xi}{dz} + \frac{d\zeta}{dx} = \tan \psi, \quad \frac{d\eta}{dz} + \frac{d\zeta}{dy} = \tan \phi.$$

§ 277. **Determination of the Strain in any Given Direction.**— Suppose we are required, knowing the strains  $\epsilon_x, \epsilon_y, \epsilon_z, \gamma_{xy}, \gamma_{xz}, \gamma_{yz}$ , to determine the strain in a direction making angles  $\alpha, \beta, \gamma$ , with  $OX, OY, OZ$  respectively. Assume our rectangular parallelopipedical particle in such a way that the diagonal from  $(x, y, z)$  to  $(x + dx, y + dy, z + dz)$  shall be in the required direction, and call the length of this diagonal  $ds$ ; then we shall have

$$(ds)^2 = (dx)^2 + (dy)^2 + (dz)^2, \quad (1)$$

$$\cos \alpha = \frac{dx}{ds}, \quad (2)$$

$$\cos \beta = \frac{dy}{ds}, \quad (3)$$

$$\cos \gamma = \frac{dz}{ds}. \quad (4)$$

Let  $\epsilon$  be the strain in the required direction ; then length of diagonal after load is applied will be

$$ds(1 + \epsilon),$$

and we shall have

$$(ds)^2(1 + \epsilon)^2 = (dx + d\xi)^2 + (dy + d\eta)^2 + (dz + d\zeta)^2,$$

or

$$(ds)^2 + 2\epsilon(ds)^2 + \epsilon^2(ds)^2 = (dx)^2 + (dy)^2 + (dz)^2 + 2(dx d\xi + dy d\eta + dz d\zeta) + (d\xi)^2 + (d\eta)^2 + (d\zeta)^2. \quad (5)$$

Now, subtracting (1) from (5), and neglecting  $\epsilon^2(ds)^2$ ,  $(d\xi)^2$ ,  $(d\eta)^2$ , and  $(d\zeta)^2$  as being very small compared with the rest, we have

$$2\epsilon(ds)^2 = 2dx d\xi + 2dy d\eta + 2dz d\zeta$$

$$\therefore \epsilon ds = \frac{dx}{ds} d\xi + \frac{dy}{ds} d\eta + \frac{dz}{ds} d\zeta, \quad (6)$$

or

$$\epsilon ds = d\xi \cos \alpha + d\eta \cos \beta + d\zeta \cos \gamma. \quad (7)$$

But

$$d\xi = \frac{d\xi}{dx} dx + \frac{d\xi}{dy} dy + \frac{d\xi}{dz} dz, \quad (8)$$

$$d\eta = \frac{d\eta}{dx} dx + \frac{d\eta}{dy} dy + \frac{d\eta}{dz} dz, \quad (9)$$

$$d\zeta = \frac{d\zeta}{dx} dx + \frac{d\zeta}{dy} dy + \frac{d\zeta}{dz} dz. \quad (10)$$

Hence, substituting these, we have, after dividing by  $ds$ , and observing (2), (3), and (4),

$$\begin{aligned} \epsilon = & \frac{d\xi}{dx} \cos^2 \alpha + \frac{d\eta}{dy} \cos^2 \beta + \frac{d\zeta}{dz} \cos^2 \gamma + \left( \frac{d\eta}{dz} + \frac{d\zeta}{dy} \right) \cos \beta \cos \gamma \\ & + \left( \frac{d\xi}{dz} + \frac{d\zeta}{dx} \right) \cos \alpha \cos \gamma + \left( \frac{d\eta}{dx} + \frac{d\xi}{dy} \right) \cos \alpha \cos \beta; \quad (11) \end{aligned}$$

or, making use of § 276, we have

$$\begin{aligned} \epsilon = & \epsilon_x \cos^2 \alpha + \epsilon_y \cos^2 \beta + \epsilon_z \cos^2 \gamma + \gamma_{yz} \cos \beta \cos \gamma \\ & + \gamma_{zx} \cos \alpha \cos \gamma + \gamma_{xy} \cos \alpha \cos \beta, \quad (12) \end{aligned}$$

which gives us the strain in any direction.

It can be shown that there are three directions, at right angles to each other, that give the maximum strains or minimum strains: and we might deduce the ellipsoid of strains, in which semi-diameters of the ellipsoid represent the strains; but we will pass on to the consideration of the stresses.

§ 278. **Stresses.** — When a body is subjected to the action of external forces, if we imagine a plane section dividing the body into two parts, the force with which one part of the body acts upon the other at this plane is called the *stress* on the plane; and, in order to know it completely, we must know its distribution and its direction at each point of the plane. If we consider a small area in this plane, including the point  $O$ , and represent the stress on this area by  $p$ , whereas the area itself is represented by  $a$ , then will the limit of  $\frac{p}{a}$ , as  $a$  approaches zero, be the intensity of the stress on the plane under consideration at the point  $O$ . Observe that we cannot speak of the stress at a certain point of a body unless we refer it to a certain plane of action: thus, if a body be in a state of strain, we do not attempt to analyze all the molecular forces with which any one

particle is acted on by its neighbors : but, when we assume a certain plane of section through the point, the stress on this plane at the point becomes recognizable in magnitude and direction ; and what the magnitude and direction of the stress at the given point is, depends upon the direction of the plane section chosen, the magnitude and direction differing for different plane sections through the point.

§ 279. **Simple Stress.** — A simple stress is merely a pull or a thrust. Assume a prismatic body, with sides parallel to  $OX$ , subjected to a pull in the direction of its length ; the magnitude of the pull being  $P$ . Assume first a plane section  $AA$  normal to the direction of  $P$ , and let area of  $AA$  be  $A$ . Then, if  $p_x$  represent the intensity of stress at any point of this plane,

$$p_x = \frac{P}{A}.$$

This, which is the intensity of the stress as distributed over a plane normal to its direction, may be called its normal intensity.

On the other hand, if we desire to ascertain the intensity of the stress on the oblique plane  $BB$ , making an angle  $\theta$  with  $AA$ , we shall have

$$\text{Area } BB = \frac{A}{\cos \theta}.$$

Hence, if  $p_r$  represent the intensity of the stress on this plane in the direction  $OX$ , we shall have

$$p_r = \frac{P}{\left(\frac{A}{\cos \theta}\right)} = \frac{P}{A} \cos \theta = p_x \cos \theta. \quad (1)$$

If we resolve this into two components, acting respectively nor-

FIG. 297.

mal and tangential to  $BB$ , and if we denote the normal intensity by  $p_n$  and the tangential by  $p_t$ , we shall have

$$p_n = p_r \cos \theta = p_x \cos^2 \theta, \quad (2)$$

$$p_t = p_r \sin \theta = p_x \cos \theta \sin \theta. \quad (3)$$

If, now, we assume another oblique plane section, perpendicular to the first, we shall obtain the normal  $p_n'$  and the tangential  $p_t'$  stress on this plane by substituting for  $\theta$ ,  $\frac{\pi}{2} - \theta$ ; hence we obtain

$$p_n' = p_x \sin^2 \theta, \quad (4)$$

$$p_t' = p_x \cos \theta \sin \theta. \quad (5)$$

Hence follows

$$p_t' = p_t;$$

or, the tangential components of a simple stress on a pair of planes at right angles to each other are equal.

§ 280. **Compound Stress.**—A compound stress may be accounted to be the resultant of a set of simple stresses, and may be analyzed into different groups of simple stresses.

**PROPOSITION.**—*Whatever be the external forces applied to a body, if through any point we pass three planes of section at right angles to each other, the tangential components of the stress on any two of these planes in directions parallel to the third must be of equal intensity.*

To prove this proposition, assume three rectangular axes, origin at  $O$ , and assume a rectangular parallelepipedical particle, as shown in the figure, so small that we may without appreciable error assume the stress on any one of the faces to be the same as that on the opposite face; resolve these stresses, i.e., the forces exerted upon the faces of the particle by the other parts of the body, into components parallel to the axes.

FIG. 298.

Let  $\sigma_x$  = intensity of normal stress on the  $x$  plane,  
 $\sigma_y$  = intensity of normal stress on the  $y$  plane,  
 $\sigma_z$  = intensity of normal stress on the  $z$  plane,  
 $\tau_{xy}$  = intensity of shearing-stress on  $x$  plane in direction  $OY$ ,  
 $\tau_{xz}$  = intensity of shearing-stress on  $x$  plane in direction  $OZ$ ,  
 $\tau_{yx}$  = intensity of shearing-stress on  $y$  plane in direction  $OX$ ,  
 $\tau_{yz}$  = intensity of shearing-stress on  $y$  plane in direction  $OZ$ ,  
 $\tau_{zx}$  = intensity of shearing-stress on  $z$  plane in direction  $OX$ ,  
 $\tau_{zy}$  = intensity of shearing-stress on  $z$  plane in direction  $OY$ .

We have thus apparently nine stresses, which must be given, in order to define the stress at the point  $O$  completely; but we will now proceed to prove that

$$\tau_{xy} = \tau_{yx}, \quad \tau_{xz} = \tau_{zx}, \quad \tau_{yz} = \tau_{zy}.$$

In the figure, the only ones of these stresses that are represented are the following:—

$$\begin{aligned} xa &= x_1a_1 = \sigma_x, \\ y\beta &= y_1\beta_1 = \sigma_y, \\ xa_2 &= x_1a_3 = \tau_{xy}, \\ y\beta_2 &= y_1\beta_3 = \tau_{yx}, \\ z\gamma &= z_1\gamma_1 = \sigma_z. \end{aligned}$$

The other four are omitted, in order not to complicate the figure.

Now, it is evident that the total normal force on the face  $AFGD$  and the normal force on the face  $OBEC$  balance each other independently, and likewise with the other normal forces.

The only forces tending to cause rotation around  $OZ$  are the equal and opposite parallel forces  $\tau_{xy}$  (area  $AFGD$ ), one acting on the face  $AFGD$ , and the other on the face  $OBEC$ ; and the equal and opposite forces  $\tau_{yx}$  (area  $FBEG$ ), one acting on the face  $FBEG$ , and the other on the face  $COAD$ .

The first pair forms a couple whose moment is  $\tau_{xy}$  (area  $AFGD$ )  $(xx_1)$ , and the second has the moment  $\tau_{yx}$  (area  $FBEG$ )  $(yy_1)$ .

But

$$\text{Area } AFGD = (FA)(zz_1), \quad \text{area } FBEG = (FB)(zz_1)$$

$$\therefore \tau_{xy}(FA)(zz_1)(xx_1) = \tau_{yx}(FB)(zz_1)(yy_1).$$

Cancelling  $zz_1$ , we have

$$\tau_{xy}(FA)(xx_1) = \tau_{yx}(FB)(yy_1).$$

But

$$FA = yy_1 \quad \text{and} \quad FB = xx_1$$

$$\therefore \tau_{xy}(xx_1)(yy_1) = \tau_{yx}(xx_1)(yy_1).$$

$$\therefore \tau_{xy} = \tau_{yx},$$

Q. E. D.

In a similar manner we can prove

$$\tau_{xz} = \tau_{zx},$$

$$\tau_{yz} = \tau_{zy}.$$

#### GENERAL REMARKS.

From what precedes, it follows, that, when we have the six stresses

$$\sigma_{x_1} \quad \sigma_{y_1} \quad \sigma_{z_1} \quad \tau_{xy_1} \quad \tau_{xz_1} \quad \tau_{yz_1}$$

or, in other words, the normal and tangential components of the stresses on three planes at right angles to each other, given, the state of stress at that point is entirely determined; and, when these are given, it is possible to determine the direction and intensity of the stress on any given plane.

Moreover, if three rectangular axes,  $OX$ ,  $OY$ , and  $OZ$ , be assumed, and the direct strains along these axes be given, and also the shearing-strain about these axes, then the direct strain in any given direction can be determined, and also the shearing-strain around this direction as an axis.

The two above-stated propositions furnish two of the fundamental propositions of the theory of elasticity, the third being the determination of the relation between the stresses and the strains.

§ 281. **Relations Governing the Variation of the Stresses at Different Points of a Body.** — If we assume a point whose co-ordinates are  $(x, y, z)$ , and a small parallelepipedical particle having this point and the point  $(x + dx, y + dy, z + dz)$  for the extremities of its diagonal, we shall have, for the edges of this particle,  $dx, dy, dz$ , respectively.

Now let the stresses at  $(x, y, z)$  be

$$\sigma_x, \sigma_y, \sigma_z, \tau_{xy}, \tau_{xz}, \tau_{yz};$$

i.e.  $\sigma_x$  denotes the normal stress on any plane perpendicular to  $OX$ , and passing through the point  $(x, y, z)$ , etc. Then, for the planes passing through  $(x + dx, y + dy, z + dz)$ , we shall have the stresses

$$\sigma_x + d\sigma_x, \sigma_y + d\sigma_y, \sigma_z + d\sigma_z, \tau_{xy} + d\tau_{xy}, \tau_{xz} + d\tau_{xz}, \tau_{yz} + d\tau_{yz}.$$

We may also have outside forces acting upon the particle in question: if such is the case, let the components of the resultant external force along the axes be respectively

$$Xdx dy dz, \quad Ydx dy dz, \quad Zdx dy dz.$$

Now impose the conditions of equilibrium between all the forces acting on the particle. To do this, place equal to zero the algebraic sum of all the forces parallel to each of the axes

respectively, the moment equations having already been incorporated in our demonstration that

$$\tau_{xy} = \tau_{yx}, \quad \tau_{xz} = \tau_{zx}, \quad \tau_{yz} = \tau_{zy}.$$

Hence we have three conditions of equilibrium, as follows:—

$$\begin{aligned} (\sigma_x + d\sigma_x - \sigma_x)dydz + (\tau_{xy} + d\tau_{xy} - \tau_{xy})dx dz + (\tau_{xz} + d\tau_{xz} - \tau_{xz})dx dy + Xdx dy dz &= 0, \\ (\sigma_y + d\sigma_y - \sigma_y)dx dz + (\tau_{xy} + d\tau_{xy} - \tau_{xy})dy dz + (\tau_{yz} + d\tau_{yz} - \tau_{yz})dy dx + Ydx dy dz &= 0, \\ (\sigma_z + d\sigma_z - \sigma_z)dx dy + (\tau_{yz} + d\tau_{yz} - \tau_{yz})dx dz + (\tau_{xz} + d\tau_{xz} - \tau_{xz})dx dy + Zdx dy dz &= 0. \end{aligned}$$

Hence, reducing, and dividing by  $dx dy dz$ , we have

$$\frac{d\sigma_x}{dx} + \frac{d\tau_{xy}}{dy} + \frac{d\tau_{xz}}{dz} + X = 0, \quad (1)$$

$$\frac{d\tau_{xy}}{dx} + \frac{d\sigma_y}{dy} + \frac{d\tau_{yz}}{dz} + Y = 0, \quad (2)$$

$$\frac{d\tau_{xz}}{dx} + \frac{d\tau_{yz}}{dy} + \frac{d\sigma_z}{dz} + Z = 0. \quad (3)$$

If the particle is in the interior of the body, so that no external forces act upon it, then  $X = Y = Z = 0$ .

Equations (1), (2), and (3) give the necessary relations which the variations of stress from point to point must satisfy in order that the conditions of equilibrium may be fulfilled.

§ 282. **Relations between the Stresses and Strains.**—Before proceeding to the general problems of composition of stresses, i.e., of determining from a sufficient number of data the stress upon any plane, we will first discuss the relations between the stresses and the strains; and we will confine ourselves to those bodies that are homogeneous, and of the same elasticity throughout.

From what we have already seen, if to a straight rod whose cross-section is  $A$  there be applied a pull  $P$  in the direction of

its length, the intensity of the stress on the cross-section will be

$$\sigma = \frac{P}{A};$$

and, if  $E$  be the tensile modulus of elasticity of the material of the rod, the strain in a direction at right angles to the cross-section, or, in other words, in the direction of the pull, will be

$$\epsilon = \frac{\sigma}{E}.$$

Now, another fact, which we have thus far taken no account of, is, that although there is no stress in a direction at right angles to the pull, or, in other words, although a section at right angles to the above-stated cross-section will have no stress upon it, yet there will be a strain in all directions at right angles to the direction of the pull: and this strain will be, for any direction at right angles to the pull,

$$\epsilon_1 = -\frac{\epsilon}{m},$$

being of the opposite kind from  $\epsilon$ ; thus, if  $\epsilon$  is extension,  $\epsilon_1$  is compression, and *vice versa*.

Hence, if, at any point  $O$  of such a rod, we assume three rectangular axes, of which  $OX$  is in the direction of the pull, and we use the notation already adopted, we shall have

$$\sigma_x = \frac{P}{A}, \quad \sigma_y = \sigma_z = \tau_{xy} = \tau_{xz} = \tau_{yz} = 0,$$

$$\epsilon_x = \frac{\sigma_x}{E}, \quad \epsilon_y = \epsilon_z = -\frac{1}{m} \frac{\sigma_x}{E} = -\frac{\epsilon_x}{m},$$

$$\gamma_{xy} = \gamma_{xz} = \gamma_{yz} = 0.$$

## MODULUS OF SHEARING ELASTICITY.

In the case of direct tension or compression, when only a simple stress is applied, we have defined the modulus of elasticity as the ratio of the stress to the strain in its own direction.

Adopting a similar definition in the case of shearing, we shall have

$$\frac{\tau_{xy}}{\gamma_{xy}} = \frac{\tau_{xz}}{\gamma_{xz}} = \frac{\tau_{yz}}{\gamma_{yz}} = G,$$

where  $G$  is the modulus of shearing elasticity.

## GENERAL RELATIONS BETWEEN STRESSES AND STRAINS.

Whenever a compound stress acts on a body at a given point, let the stresses be

$$\sigma_x, \sigma_y, \sigma_z, \tau_{xy}, \tau_{xz}, \tau_{yz};$$

then we shall have, for the strain in the direction  $OX$ ,

$$\epsilon_x = \frac{\sigma_x}{E} - \frac{1}{m} \frac{\sigma_y}{E} - \frac{1}{m} \frac{\sigma_z}{E}, \quad \gamma_{xy} = \frac{\tau_{xy}}{G},$$

$$\epsilon_y = \frac{\sigma_y}{E} - \frac{1}{m} \frac{\sigma_x}{E} - \frac{1}{m} \frac{\sigma_z}{E}, \quad \gamma_{xz} = \frac{\tau_{xz}}{G},$$

$$\epsilon_z = \frac{\sigma_z}{E} - \frac{1}{m} \frac{\sigma_x}{E} - \frac{1}{m} \frac{\sigma_y}{E}, \quad \gamma_{yz} = \frac{\tau_{yz}}{G}.$$

This enables us to determine the strains in terms of the stresses, as soon as the values of  $E$ ,  $G$ , and  $m$  are known from experiment, for the material under consideration.

If, on the other hand, the stresses be required in terms of the strains, we can consider  $\epsilon_x, \epsilon_y, \epsilon_z, \gamma_{xy}, \gamma_{xz}, \gamma_{yz}$  as known, and determine  $\sigma_x, \sigma_y, \sigma_z, \tau_{xy}, \tau_{yz}, \tau_{xz}$  from the above equations.

We thus obtain

$$E\epsilon_x = \sigma_x - \frac{\sigma_y + \sigma_z}{m}, \quad (1)$$

$$E\epsilon_y = \sigma_y - \frac{\sigma_x + \sigma_z}{m}, \quad (2)$$

$$E\epsilon_z = \sigma_z - \frac{\sigma_x + \sigma_y}{m}; \quad (3)$$

and, by solving these equations for the stresses, we have

$$\sigma_x = \frac{m}{m+1} E \left( \epsilon_x + \frac{\epsilon_x + \epsilon_y + \epsilon_z}{m-2} \right), \quad (4)$$

$$\sigma_y = \frac{m}{m+1} E \left( \epsilon_y + \frac{\epsilon_x + \epsilon_y + \epsilon_z}{m-2} \right), \quad (5)$$

$$\sigma_z = \frac{m}{m+1} E \left( \epsilon_z + \frac{\epsilon_x + \epsilon_y + \epsilon_z}{m-2} \right), \quad (6)$$

and also

$$\tau_{xy} = G\gamma_{xy} \quad (7) \quad \tau_{xz} = G\gamma_{xz}, \quad (8) \quad \tau_{yz} = G\gamma_{yz}. \quad (9)$$

These equations express the stresses in terms of the strains.

The three last might be written as follows (see § 276):—

$$\tau_{xy} = G \left( \frac{d\xi}{dy} + \frac{d\eta}{dx} \right), \quad (10)$$

$$\tau_{xz} = G \left( \frac{d\xi}{dz} + \frac{d\zeta}{dx} \right), \quad (11)$$

$$\tau_{yz} = G \left( \frac{d\eta}{dz} + \frac{d\zeta}{dy} \right), \quad (12)$$

as these forms are often convenient.

§ 283. **Case when  $\sigma_s = 0$ .**—Inasmuch as there are many cases in practice where the stress is all parallel to one plane, and where, consequently, the stress on any plane parallel to this plane has no normal component, it will be convenient to have the reduced forms of equations (4), (5), and (6) which apply in this case.

Let the plane to which the stresses are parallel be the  $Z$  plane; then  $\sigma_z = 0$ . Then equation (6) becomes

$$\epsilon_z + \frac{\epsilon_x + \epsilon_y + \epsilon_z}{m - 2} = 0$$

$$\therefore \epsilon_z = -\frac{\epsilon_x + \epsilon_y}{(m - 2)(m - 1)};$$

and, substituting this value of  $\epsilon_z$  in (4) and (5), and reducing, we obtain

$$\sigma_x = \frac{m}{m + 1} E \left( \epsilon_x + \frac{\epsilon_x + \epsilon_y}{m - 1} \right), \quad (1)$$

$$\sigma_y = \frac{m}{m + 1} E \left( \epsilon_y + \frac{\epsilon_x + \epsilon_y}{m - 1} \right), \quad (2)$$

which are the required forms.

The other three equations, viz., —

$$\tau_{xy} = G\gamma_{xy}, \quad \tau_{xz} = G\gamma_{xz}, \quad \tau_{yz} = G\gamma_{yz},$$

remain the same as before.

§ 284. Values of  $E$ ,  $G$ , and  $m$ . — These three constants need to be known, to use the relations developed above.

1°. As to  $E$ , this is the modulus of elasticity for tension, and has been determined experimentally for the various materials, as has been already explained. Moreover, it has also been shown experimentally, that, with moderate loads, the modulus of elasticity for compression is nearly identical with that for tension in cast-iron, wrought-iron, and steel.

2°. As to  $m$ , in those few applications that Professor Rankine gives of his theory of internal stress, such as the case of combined twisting and bending, he determines the greatest intensity of the stress acting; and his criterion is, that this shall be kept within the working-strength of the material. This is equivalent to assuming  $m = \infty$ . The more modern writers,

such as Grashof and others, take account of the fact that  $m$  has a finite value, and make their criterion that the greatest strain shall be kept within the quotient obtained by dividing the working-strength by the modulus of elasticity of the material.

Thus, if  $f$  is the working-strength, and  $\sigma_1$  the greatest stress, and  $\epsilon_1$  the greatest strain, Rankine's criterion of safety is

$$\sigma_1 \leq f;$$

whereas the more modern criterion is

$$E\epsilon_1 \leq f.$$

The resulting formulæ differ in each case; and, as has been stated, those of Rankine could be derived from the more general ones by making

$$\frac{1}{m} = 0 \quad \text{or} \quad m = \infty,$$

which is never the case.

As to the value of  $m$ , but few experiments have been made. Those of Wertheim give, for brass, 2.94; for wrought-iron, 3.64.

The values  $m = 3$  and  $m = 4$  are those most commonly adopted, so that

$$\frac{1}{m} = \frac{1}{3} \quad \text{or} \quad \frac{1}{m} = \frac{1}{4}.$$

3°. The value of  $G$ , the shearing-modulus of elasticity, i.e., the ratio of the stress to the strain for shearing, has been determined experimentally, and has generally been found to be about two-fifths that for tension.

According to the theory of elasticity, we must have

$$G = \frac{1}{2} \frac{m}{m + 1} E,$$

as may be proved as follows:—

Assume a square particle whose side is  $a$ , and let a simple normal stress  $\sigma$  be applied at the face  $AB$ ; then we shall have, on the planes  $BD$  and  $AC$ , a shearing-stress (§ 279)

$$\tau = \sigma \sin 45^\circ \cos 45^\circ = \frac{1}{2}\sigma.$$

On the other hand, if we let

$$\epsilon = \frac{\sigma}{E},$$

FIG. 299.

the strain of the particle in the direction  $AD$  will be  $\epsilon$ , while that in the direction  $AB$  will be  $-\frac{\epsilon}{m}$ ; hence the particle will become a rectangle, the side  $AD$  changing its length from  $a$  to  $a + a\epsilon$ , and side  $AB$  changing from  $a$  to  $a - \frac{a\epsilon}{m}$ .

The diagonals will no longer be at right angles to each other; and, if we denote by  $\alpha$  the angle by which their angle differs from a right angle, we shall have, for the shearing-strain on the planes  $AC$  and  $BD$ ,

$$\gamma = \tan \alpha.$$

But, after the distortion, the angle  $ADB$  will become

$$\frac{1}{2}\left(\frac{\pi}{2} - \alpha\right)$$

$$\therefore \tan\left(\frac{\pi}{4} - \frac{\alpha}{2}\right) = \frac{1 - \tan \frac{\alpha}{2}}{1 + \tan \frac{\alpha}{2}} = \frac{a - \frac{a\epsilon}{m}}{a + a\epsilon} = \frac{1 - \frac{\epsilon}{m}}{1 + \epsilon};$$

therefore, dividing, and carrying the division only to terms of the first degree, we have

$$1 - 2 \tan \frac{\alpha}{2} = 1 - \left(1 + \frac{1}{m}\right)\epsilon$$

$$\therefore 2 \tan \left(\frac{\alpha}{2}\right) = \frac{m + 1}{m} \epsilon.$$

But

$$\gamma = \tan \alpha = 2 \tan \frac{\alpha}{2} \text{ nearly}$$

$$\therefore \gamma = \frac{m + 1}{m} \epsilon$$

$$\therefore \frac{\tau}{\gamma} = \frac{\frac{1}{2}\sigma}{\frac{m + 1}{m} \epsilon} = \frac{1}{2} \frac{m}{m + 1} \left( \frac{\sigma}{\epsilon} \right);$$

but

$$\frac{\tau}{\gamma} = G \quad \text{and} \quad \frac{\sigma}{\epsilon} = E$$

$$\therefore G = \frac{1}{2} \frac{m}{m + 1} E.$$

§ 285. **Conjugate Stresses.** — If the stress on a given plane at a given point of a body be in a given direction, the stress at the same point on a plane parallel to that direction will be parallel to the given plane. Let  $YOY$  represent, in section, a given plane, and let the stress on that plane be in the direction  $XOX$ .

Consider a small prism  $ABCD$  within a body, the sides of whose base are parallel respectively to  $XOX$  and  $YOY$ . The forces on the plane  $AB$  are counterbalanced by the forces on the plane  $DC$ ; the resultants of each of these sets being equal and opposite, and acting along a line passing through  $O$ . Hence the forces acting on the planes  $AD$  and  $BC$  must be balanced entirely independently of any of the forces on  $AB$  or  $DC$ : and this can be the case only when their direction is parallel to  $YOY$ ; for otherwise their resultants, though equal in magnitude and opposite in direction, would not be directly opposite, but would form a couple, and, as there is no equal and opposite couple furnished by the forces on the other faces, equilibrium could not exist under this supposition.

§ 286. **Composition of Stresses.** — The general problem of the composition of stresses may be stated as follows:—

Knowing the stresses at a given point of a strained body on three planes passing through that point, to find the stress at the same point on any other plane, also passing through the same point. The stresses on the three given planes are not entirely independent; in other words, we could not give the stresses on these three planes, in magnitude and direction, at random, and expect to find the problem a possible one. Thus, suppose that the planes are at right angles to each other, we have already seen that we have the right to give their three normal components,  $\sigma_x$ ,  $\sigma_y$ , and  $\sigma_z$ , and the three tangential,  $\tau_{xy}$ ,  $\tau_{yz}$ , and  $\tau_{zx}$  and that  $\tau_{yx} = \tau_{xy}$  etc. We will now proceed to special cases.

§ 287. Problem. — Given the three planes of action of the stress as the  $x$ ,  $y$ , and  $z$  plane respectively, and given the normal and tangential components of the stresses on these planes, viz.,  $\sigma_x$ ,  $\sigma_y$ ,  $\sigma_z$ ,  $\tau_{xy}$ ,  $\tau_{yz}$ , and  $\tau_{zx}$  to find the intensity and direction of the stress on a plane whose normal makes with  $OX$ ,  $OY$ , and  $OZ$  the angles  $\alpha$ ,  $\beta$ , and  $\gamma$  respectively, where, of course,  $\cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1$ .

Draw the line  $ON$ , making angles  $\alpha$ ,  $\beta$ , and  $\gamma$  with  $OX$ ,  $OY$ , and  $OZ$  respectively; then draw near  $O$  the plane  $ABC$  perpendicular to  $ON$ . It has the direction of the required plane, and cuts off intercepts  $OA$ ,  $OB$ , and  $OC$  on the axes; and, moreover, we shall have, from trigonometry, the relations,

$$\begin{aligned} \text{Area } BOC &= (ABC) \cos \alpha, \\ \text{Area } AOC &= (ABC) \cos \beta, \\ \text{Area } AOB &= (ABC) \cos \gamma. \end{aligned}$$

FIG. 300.

Now consider the conditions of equilibrium of the tetrahedron  $OABC$ . The stress on  $ABC$  must be equal and directly

opposed to the resultant of the stresses on the three faces  $AOC$ ,  $BOC$ , and  $AOB$ . Now let us proceed to find this resultant.

In the direction  $OX$  we have the force

$$\begin{aligned}\sigma_x(BOC) + \tau_{xz}(AOB) + \tau_{xy}(AOC) \\ = (ABC)(\sigma_x \cos \alpha + \tau_{xy} \cos \beta + \tau_{xz} \cos \gamma).\end{aligned}$$

Lay off  $OD$  to represent this quantity. In the same way represent the force in the direction  $OY$  by

$$\begin{aligned}OE = \sigma_y(AOC) + \tau_{yz}(BOA) + \tau_{xy}(BOC) \\ = (ABC)(\sigma_y \cos \beta + \tau_{xy} \cos \alpha + \tau_{yz} \cos \gamma),\end{aligned}$$

and that in the direction  $OZ$  by

$$\begin{aligned}OF = \sigma_z(AOB) + \tau_{yz}(BOC) + \tau_{xz}(AOC) \\ = ABC(\sigma_z \cos \gamma + \tau_{yz} \cos \alpha + \tau_{xz} \cos \beta).\end{aligned}$$

Now compound these three forces, and we have, as resultant force,

$$R = OG = \sqrt{OD^2 + OE^2 + OF^2},$$

and as resultant intensity

$$\begin{aligned}\sigma = \frac{R}{ABC} &= \frac{\sqrt{OD^2 + OE^2 + OF^2}}{ABC} \\ &= \sqrt{\{\sigma_x \cos \alpha + \tau_{xy} \cos \beta + \tau_{xz} \cos \gamma\}^2 \\ &\quad + \{\sigma_y \cos \beta + \tau_{xy} \cos \alpha + \tau_{yz} \cos \gamma\}^2 \\ &\quad + \{\sigma_z \cos \gamma + \tau_{yz} \cos \alpha + \tau_{xz} \cos \beta\}^2\} \\ &= \sqrt{\{\sigma_x^2 \cos^2 \alpha + \sigma_y^2 \cos^2 \beta + \sigma_z^2 \cos^2 \gamma \\ &\quad + \tau_{xy}^2 (\cos^2 \alpha + \cos^2 \beta) + \tau_{xz}^2 (\cos^2 \alpha + \cos^2 \gamma) \\ &\quad + \tau_{yz}^2 (\cos^2 \beta + \cos^2 \gamma) + 2\sigma_x (\tau_{xy} \cos \beta + \tau_{xz} \cos \gamma) \cos \alpha \\ &\quad + 2\sigma_y (\tau_{xy} \cos \alpha + \tau_{yz} \cos \gamma) \cos \beta \\ &\quad + 2\sigma_z (\tau_{yz} \cos \alpha + \tau_{xz} \cos \beta) + 2\tau_{xy} \tau_{xz} \cos \beta \cos \gamma \\ &\quad + 2\tau_{xy} \tau_{yz} \cos \alpha \cos \gamma + 2\tau_{yz} \tau_{xz} \cos \alpha \cos \beta\}};\end{aligned}$$

the direction being given by the angles,  $\alpha_r$ ,  $\beta_r$  and  $\gamma_r$  where

$$\cos \alpha_r = \frac{OD}{R}, \quad \cos \beta_r = \frac{OE}{R}, \quad \cos \gamma_r = \frac{OF}{R}.$$

§ 288. **Stresses Parallel to a Plane.** — To solve the same problem when there is no stress in the direction  $OZ$ , and when the new plane is perpendicular to  $XOY$ , or, in other words, in the case when the planes of action are all perpendicular to one plane, to which the stresses are all parallel: we then have

$$\sigma_z = \tau_{xz} = \tau_{yz} = 0 \quad \text{and} \quad \beta = 90^\circ - \alpha,$$

and hence

$$\sigma = \sqrt{\sigma_x^2 \cos^2 \alpha + \sigma_y^2 \sin^2 \alpha + \tau_{xy}^2} + 2(\sigma_x + \sigma_y)\tau_{xy} \cos \alpha \sin \alpha.$$

Or we may proceed as follows:—

Let the normal intensity of the stress on the  $x$  plane (i.e., that perpendicular to  $OX$ ) be  $\sigma_x$ , that on the  $y$  plane  $\sigma_y$ , and the tangential intensity  $\tau_{xy}$ . Let  $ON$  be the direction of the normal to the plane on which the stress is to be determined, and let the angle  $XON = \alpha$ . Then let the plane  $AB$  be drawn perpendicular to  $ON$ , and let us consider the equilibrium of the forces exerted by the other parts of the body upon the triangular prism whose base is  $ABO$  and altitude unity.

FIG. 301.

If we compound the forces acting on the faces  $AO$  and  $OB$ , we shall have, in their resultant, the total force on the face  $AB$  in magnitude and direction. Moreover, we have the relations,

$$\text{Area } OB = \text{area } AB \cos \alpha \quad \text{and} \quad \text{Area } OA = \text{area } AB \sin \alpha.$$

$$\text{Force acting on } OB \text{ in direction } OX = \sigma_x(OB),$$

$$\text{Force acting on } OB \text{ in direction } OY = \tau_{xy}(OB),$$

$$\text{Force acting on } OA \text{ in direction } OX = \tau_{xy}(OA),$$

$$\text{Force acting on } OA \text{ in direction } OY = \sigma_y(OA).$$

Hence, if we lay off

$$OD = \sigma_x(OB) + \tau_{xy}(OA) \quad \text{and} \quad OC = \sigma_y(OA) + \tau_{xy}(OB),$$

then will  $OD$  represent the total force acting in the direction  $OX$ , and  $OC$  will represent the total force acting in the direction  $OY$ .

Compounding these, we shall have  $OE$  as the resultant total force on the face  $AB$ , and  $\frac{OE}{AB}$  will represent its intensity.

To deduce the analytical values, we have

$$OD = \sigma_x(OB) + \tau_{xy}(OA) = (AB)(\sigma_x \cos \alpha + \tau_{xy} \sin \alpha),$$

$$OC = \sigma_y(OA) + \tau_{xy}(OB) = (AB)(\sigma_y \sin \alpha + \tau_{xy} \cos \alpha)$$

$$\therefore OE = \sqrt{OD^2 + OC^2}$$

$$\begin{aligned} &= AB \sqrt{(\sigma_x \cos \alpha + \tau_{xy} \sin \alpha)^2 + (\sigma_y \sin \alpha + \tau_{xy} \cos \alpha)^2} \\ &= AB \sqrt{\{\sigma_x^2 \cos^2 \alpha + \sigma_y^2 \sin^2 \alpha + 2\tau_{xy} \cos \alpha \sin \alpha (\sigma_x + \sigma_y) \\ &\quad + \tau_{xy}^2 (\cos^2 \alpha + \sin^2 \alpha)\}}. \end{aligned}$$

Or, if  $\sigma_r$  represent the resultant intensity on the plane  $AB$ , and  $\alpha_r$  the angle this resultant makes with  $OX$ , we shall have

$$\begin{aligned} \sigma_r = \sqrt{\{\sigma_x^2 \cos^2 \alpha + \sigma_y^2 \sin^2 \alpha \\ + 2\tau_{xy}(\sigma_x + \sigma_y) \cos \alpha \sin \alpha + \tau_{xy}^2\}}, \quad (1) \end{aligned}$$

and

$$\cos \alpha_r = \frac{OD}{OE} \quad \text{and} \quad \sin \alpha_r = \frac{OC}{OE}.$$

Moreover, it is sometimes desirable to resolve the stress into normal and tangential components. If this be done, and if  $\sigma$  and  $\tau$  represent respectively the normal and tangential components, we shall have

$$\sigma = \frac{OF}{AB} \quad \text{and} \quad \tau = \frac{EF}{AB};$$

but

$$OF = OD \cos \alpha + ED \sin \alpha \quad \text{and} \quad EF = ED \cos \alpha - OD \sin \alpha$$

$$\begin{aligned} \therefore \sigma &= \frac{OD}{AB} \cos \alpha + \frac{OC}{AB} \sin \alpha \\ &= \sigma_x \cos^2 \alpha + \sigma_y \sin^2 \alpha + 2\tau_{xy} \cos \alpha \sin \alpha \quad (2) \end{aligned}$$

and

$$\begin{aligned} \tau &= \frac{OC}{AB} \cos \alpha - \frac{OD}{AB} \sin \alpha \\ &= (\sigma_y - \sigma_x) \cos \alpha \sin \alpha + \tau_{xy} (\cos^2 \alpha - \sin^2 \alpha) \\ &= \left( \frac{\sigma_y - \sigma_x}{2} \right) \sin 2\alpha + \tau_{xy} \cos 2\alpha. \quad (3) \end{aligned}$$

§ 289. **Principal Stresses.**— It will next be shown, that, whatever be the state of stress in a body, provided the stresses are all parallel to one plane, the planes of action being all taken perpendicular to this plane, there are always two planes, at right angles to each other, on which there is no tangential stress; these two planes being called the planes of principal stress, the stress on one of these planes being greater, and the other less, than that on any other plane through the same point.

To prove the above, it will be necessary only in the last case, which is a perfectly general one, to determine for what values of  $\alpha$  the value of  $\tau$  is zero, and whether these values of  $\alpha$  are always possible. We have

$$\tau = \frac{\sigma_y - \sigma_x}{2} \sin 2\alpha + \tau_{xy} \cos 2\alpha;$$

and, if we put this equal to zero, we have

$$\frac{\sin 2\alpha}{\cos 2\alpha} = \tan 2\alpha = \frac{2\tau_{xy}}{\sigma_x - \sigma_y};$$

and this gives us, for all values of  $\sigma_x$ ,  $\sigma_y$ , and  $\tau_{xy}$ , two possible values for  $2\alpha$ , differing from each other by  $180^\circ$ , hence two values for  $\alpha$  differing by  $90^\circ$ . Hence follows the first part of the proposition.

The latter part — that these are the planes of the greatest and least stresses — will be shown by differentiating the value of  $\sigma_r^2$ , and putting the first differential co-efficient equal to zero; and, as this gives us

$$\begin{aligned} & 2\sigma_x^2 \cos \alpha \sin \alpha + 2\sigma_y^2 \cos \alpha \sin \alpha \\ & + 2\tau_{xy}(\sigma_x + \sigma_y)(\cos^2 \alpha - \sin^2 \alpha) \\ & = 2(\sigma_x + \sigma_y)\{(\sigma_y - \sigma_x) \cos \alpha \sin \alpha + \tau_{xy}(\cos^2 \alpha - \sin^2 \alpha)\} \\ & = 0, \end{aligned}$$

therefore we have the same condition for the maximum and minimum stresses as we have for the planes of no tangential stress.

It follows that the determination of the greatest and least stresses at any one point of a body is identical with the determination of the principal stresses; and it will be necessary, whenever the stresses on any two planes are given, to be able to determine the principal stresses, as one of these is the greatest stress at that point of the body, and the other the least.

§ 290. **Determination of Principal Stresses.** — When the stress is all parallel to one plane, viz., the  $x$  plane, and when the stresses on two planes at right angles to each other are given, i.e., their normal and tangential components, we may be required to determine the principal stresses. Proceed as follows: Given normal stresses on  $X$  and  $Y$  planes respectively,  $\sigma_x$  and  $\sigma_y$ , and tangential stress on each plane  $\tau_{xy}$ , to find principal stresses.

From § 288 we have, for a plane whose normal makes an angle  $\alpha$  with  $OX$ ,

$$\sigma_r = \sqrt{\sigma_x^2 \cos^2 \alpha + \sigma_y^2 \sin^2 \alpha + 2\tau_{xy}(\sigma_x + \sigma_y)\cos \alpha \sin \alpha + \tau_{xy}^2}, \quad (1)$$

$$\sigma_n = \sigma_x \cos^2 \alpha + \sigma_y \sin^2 \alpha + 2\tau_{xy} \cos \alpha \sin \alpha, \quad (2)$$

$$\tau = \tau_{xy}(\cos^2 \alpha - \sin^2 \alpha) - (\sigma_x - \sigma_y)\cos \alpha \sin \alpha, \quad (3)$$

or

$$\tau = \tau_{xy} \cos 2\alpha - \frac{\sigma_x - \sigma_y}{2} \sin 2\alpha. \quad (4)$$

Now, the condition that the plane shall be a plane of principal stress is, that  $\tau = 0$ . Hence write

$$\tau_{xy}(\cos^2 \alpha - \sin^2 \alpha) - (\sigma_x - \sigma_y) \cos \alpha \sin \alpha = 0,$$

find  $\alpha$ , and substitute its value in (2), and we shall have the principal stresses. The operation may be performed as follows; viz., —

From (3) we have

$$(a) \quad 2 \cos^2 \alpha - 1 = \frac{\sigma_x - \sigma_y}{\tau_{xy}} \cos \alpha \sin \alpha$$

$$\therefore \cos^2 \alpha = \frac{1}{2} \left\{ 1 + \frac{\sigma_x - \sigma_y}{\tau_{xy}} \cos \alpha \sin \alpha \right\}.$$

$$(b) \quad 1 - 2 \sin^2 \alpha = \frac{\sigma_x - \sigma_y}{\tau_{xy}} \cos \alpha \sin \alpha$$

$$\therefore \sin^2 \alpha = \frac{1}{2} \left\{ 1 - \frac{\sigma_x - \sigma_y}{\tau_{xy}} \cos \alpha \sin \alpha \right\}.$$

Hence

$$\sigma_n = \frac{\sigma_x + \sigma_y}{2} + \frac{\cos \alpha \sin \alpha}{2} \left\{ \frac{\sigma_x^2 - 2\sigma_x \sigma_y + \sigma_y^2}{\tau_{xy}} + 4\tau_{xy} \right\}$$

or

$$\sigma_n = \frac{\sigma_x + \sigma_y}{2} + \frac{\cos \alpha \sin \alpha}{2\tau_{xy}} \{ (\sigma_x - \sigma_y)^2 + 4\tau_{xy}^2 \}.$$

But we have, since (4) equals zero,

$$\tan 2\alpha = \frac{2\tau_{xy}}{\sigma_x - \sigma_y}$$

$$\therefore \sin 2\alpha = 2 \sin \alpha \cos \alpha = \frac{\pm 2\tau_{xy}}{\sqrt{(\sigma_x - \sigma_y)^2 + 4\tau_{xy}^2}},$$

Hence substitute for  $\cos \alpha \sin \alpha$  its value, and

$$\sigma_n = \frac{\sigma_x + \sigma_y}{2} \pm \frac{1}{2} \sqrt{(\sigma_x - \sigma_y)^2 + 4\tau_{xy}^2}, \quad (5)$$

which gives us the magnitudes of the principal stresses; the plus sign corresponding to the greater, and the minus sign to the less.

#### EXAMPLES.

1. Let, in the last section,  $\sigma_y = 0$ , and find the principal stresses. Here we have

$$\tan 2\alpha = \frac{2\tau_{xy}}{\sigma_x}$$

and

$$\sigma_n = \frac{\sigma_x}{2} \pm \frac{1}{2} \sqrt{\sigma_x^2 + 4\tau_{xy}^2}.$$

2. Given two principal stresses, to find the stress on a plane whose normal makes an angle  $\alpha$  with  $OX$ .

In this case  $\tau_{xy} = 0$ .

Hence we have the case of § 288, with the reduction of making  $\tau_{xy} = 0$ . We may therefore obtain the result by substitution in the results of § 288, or we may proceed as follows:—

(a) Find stress on new plane in direction  $OX$ ; this will be, § 279,

$$\sigma_x \cos \alpha.$$

(b) Find stress on new plane in direction  $OY$ ; this will be, § 279,

$$\sigma_y \sin \alpha.$$

(c) Compound the two, and the resultant is

$$\sigma_r = \sqrt{\sigma_x^2 \cos^2 \alpha + \sigma_y^2 \sin^2 \alpha}. \quad (1)$$

(d) Normal component of  $\sigma_x \cos \alpha$  is

$$\sigma_x \cos^2 \alpha.$$

(e) Normal component of  $\sigma_y \sin \alpha$  is

$$\sigma_y \sin^2 \alpha.$$

(f) Add, and we have, for normal stress,

$$\sigma_n = \sigma_x \cos^2 a + \sigma_y \sin^2 a. \quad (2)$$

(g) Tangential component of  $\sigma_x \cos a$  is

$$-\sigma_x \cos a \sin a.$$

(h) Tangential component of  $\sigma_y \sin a$  is

$$+\sigma_y \cos a \sin a.$$

(k) Add, and we have, for tangential stress,

$$\tau = (\sigma_y - \sigma_x) \cos a \sin a. \quad (3)$$

§ 291. **Ellipse of Stress.**—In the case above, i.e., when the two principal stresses are  $\sigma_x$  and  $\sigma_y$  respectively, if we represent them graphically by  $OA = \sigma_x$  and  $OB = \sigma_y$ , and let  $CD$  be the plane on which the stress is required, its normal making with  $OX$  the angle  $XON = a$ , then, from what has been shown, if  $OR$  represent the intensity of the resultant stress on this plane, we shall have

$$OR = \sigma_r = \sqrt{\sigma_x^2 \cos^2 a + \sigma_y^2 \sin^2 a};$$

and, moreover,

$$OE = \sigma_x \cos a, \quad OF = \sigma_y \sin a.$$

If we denote these by  $x$  and  $y$  respectively, letting  $(x, y)$  be the point  $R$ , i.e., the extremity of the line representing the stress on  $AB$ , then

$$x = \sigma_x \cos a, \quad y = \sigma_y \sin a,$$

$$\therefore \left(\frac{x}{\sigma_x}\right)^2 = \cos^2 a \quad \text{and} \quad \left(\frac{y}{\sigma_y}\right)^2 = \sin^2 a$$

$$\therefore \frac{x^2}{\sigma_x^2} = \frac{y^2}{\sigma_y^2} = 1,$$

FIG. 302.

which is the equation of an ellipse whose semi-axes are  $\sigma_x$  and  $\sigma_y$ , respectively; hence the stress on any plane will be represented by some semi-diameter of the ellipse.

#### SPECIAL CASES.

I. When the two given stresses are equal, or  $\sigma_x = \sigma_y$ , then

$$\sigma_r = \sqrt{\sigma_x^2 \cos^2 a + \sigma_y^2 \sin^2 a} = \sigma_x$$

and

$$\cos a_r = \frac{\sigma_x \cos a}{\sigma_x} = \cos a \quad \text{and} \quad \sin a_r = \sin a;$$

therefore the stress is of the same intensity on all planes, and always normal to the plane.

II. When the two given stresses are equal in magnitude but opposite in sign, or  $\sigma_y = -\sigma_x$ , then

$$\sigma_r = \sigma_x$$

But

$$\cos a_r = \cos a \quad \text{and} \quad \sin a_r = -\sin a,$$

hence

$$a_r = -a;$$

therefore the stress on any plane whose normal makes an angle  $a$  with  $OX$  is of the same intensity  $\sigma_x$ , but makes an angle equal to  $a$  with  $OX$  on the side opposite to that of the normal to the plane.

PROBLEM. — A pair of principal stresses being given, to find the positions of the planes on which the shear is greatest.

*Solution.* — Let  $\tau = (\sigma_y - \sigma_x) \sin a \cos a = \max$ .

Therefore differentiate, and

$$\cos^2 a - \sin^2 a = 0$$

$$\therefore \cos a = \pm \sin a \quad \therefore a = 45^\circ \text{ or } 135^\circ.$$

§ 292. **Some Special Modes of Solution of some Problems.** — The case where two principal stresses,  $\sigma_x$  and  $\sigma_y$ , are given, to find the stress on any plane whose normal makes an angle  $\alpha$  with  $OX$ , may be solved as follows, graphically:—

Let, Fig. 302,  $\sigma_x = OA$ , and  $\sigma_y = OB$ . Let  $XON = \alpha$ .

Now,

$$\sigma_y = \frac{\sigma_y + \sigma_x}{2} + \frac{\sigma_y - \sigma_x}{2},$$

$$\sigma_x = \frac{\sigma_y + \sigma_x}{2} - \frac{\sigma_y - \sigma_x}{2}.$$

Hence, instead of proceeding at once to find the resultant stress on  $CD$  due to the action of  $\sigma_x$  and  $\sigma_y$ , we may first find that due to the action of the two equal principal stresses of the same kind,

$$\frac{\sigma_y + \sigma_x}{2},$$

then that due to the pair

$$\frac{\sigma_y - \sigma_x}{2} \quad \text{and} \quad -\frac{\sigma_y - \sigma_x}{2},$$

and then the resultant of these two resultants.

The first resultant will be evidently laid off on  $ON$ , and equal in magnitude to  $\frac{\sigma_y + \sigma_x}{2}$ ; hence let  $OM = \frac{\sigma_y + \sigma_x}{2}$ , and  $OM$  will be the first resultant.

The second resultant will be of magnitude  $\frac{\sigma_y - \sigma_x}{2}$ , and will have a direction  $MR$  such that the angle  $NMS = SMR$ .

Hence, laying off this angle, and making  $MR = \frac{\sigma_y - \sigma_x}{2}$ , we shall have for the final resultant,  $OR$ , as before.

This construction will be useful in the following case:—

To find the most oblique stress, we must find for what value of  $\alpha$  the angle  $MOR$  is greatest. This will be made

evident if we observe, that, for all positions of the plane, the triangle  $OMR$  has always  $OM = \frac{\sigma_y + \sigma_x}{2}$ , and  $MR = \frac{\sigma_y - \sigma_x}{2}$ ; both of constant length. Hence, if, with  $M$  as a centre and  $MR$  as a radius, a circle were described, and a tangent were drawn from  $O$  to this circle, the point of tangency being taken for  $R$ , then will  $OR$  be the most oblique stress; i.e., the stress is most oblique when  $ORM = 90^\circ$ . Therefore greatest obliquity =

$$\sin^{-1} \frac{\sigma_y - \sigma_x}{\sigma_y + \sigma_x}.$$

§ 293. **Converse of the Ellipse of Stress.** — The converse of the ellipse of stress would be the following problem: Given any two planes passing through the point in question; given the intensities and directions of the stresses on these planes, — to find the principal stresses in magnitude and in direction.

The first step to be taken is, to assure ourselves that the conditions are not incompatible, as they are liable to be if the planes and stresses are taken at random. The test of this question is, to resolve each stress into two components, respectively parallel to the two planes; and, if the conditions are not inconsistent, the component of each stress along the plane on which it acts must be equal. The proof of this statement can be made in a similar way to that used in proving that the intensities of the shearing-stresses on two planes at right angles to each other are equal. If, upon applying this test, we find that the conditions are not inconsistent, we may proceed as follows:—

Suppose  $CD$  (Fig. 302) were the given plane, and  $OR$  the stress upon it, and suppose the position of the principal axes,  $OX$  and  $OY$ , and, indeed, all the rest of the figure, were absent, i.e., not known. Now, we can easily draw the normal  $ON$ ; and, if we could determine upon it the point  $M$  such that  $OM$

should be one-half the sum of the principal stresses, we should be able to reproduce the whole figure. Hence we will devote ourselves to the determination of the position of the point  $M$ .

Let  $OB = p$  = stress on plane  $CD$ .

Let stress on the other given plane be  $p_1$ .

Let  $NOR = \theta$  = obliquity of  $p$ .

Let  $\theta_1$  = obliquity of  $p_1$ .

Then we have

$$MR^2 = OR^2 + OM^2 - 2OM \cdot OR \cos \theta;$$

or, if  $\sigma_x$  and  $\sigma_y$  denote the (unknown) magnitudes of the principal stresses,

$$\left(\frac{\sigma_y - \sigma_x}{2}\right)^2 = p^2 + \left(\frac{\sigma_x + \sigma_y}{2}\right)^2 - 2\left(\frac{\sigma_x + \sigma_y}{2}\right)p \cos \theta. \quad (1)$$

From the triangle constructed in the same way, with the stress on the other plane, we should have

$$\left(\frac{\sigma_y - \sigma_x}{2}\right)^2 = p_1^2 + \left(\frac{\sigma_x + \sigma_y}{2}\right)^2 - 2\left(\frac{\sigma_x + \sigma_y}{2}\right)p_1 \cos \theta_1. \quad (2)$$

Hence, by subtraction,

$$p^2 - p_1^2 = 2\left(\frac{\sigma_x + \sigma_y}{2}\right)(p \cos \theta - p_1 \cos \theta_1) \quad (3)$$

$$\therefore \frac{\sigma_x + \sigma_y}{2} = \frac{p^2 - p_1^2}{2(p \cos \theta - p_1 \cos \theta_1)}. \quad (4)$$

Having thus found  $\frac{\sigma_x + \sigma_y}{2}$ , we can next find, from either

(1) or (2), the value of  $\frac{\sigma_y - \sigma_x}{2}$ .

Now, therefore, we know  $OM$  and  $MR$ , and hence we can lay off this value of  $OM$ , and complete the triangle  $OMR$ ; then

bisect the angle  $NMR$ , and the line  $MS$  is parallel to the axis of greater principal stress. Hence draw  $OY$  parallel to  $MS$ , and  $OX$  perpendicular to  $OY$ , and lay off on  $OY$

$$OB = \sigma_y = \frac{OM + MR}{2},$$

and on  $OX$

$$OA = \sigma_x = \frac{OM - MR}{2},$$

and the problem is solved.

§ 294. **Case of any Stresses in Space.**—In the case of stress which is not all parallel to one plane, we should find that it is always possible, no matter how complicated the state of stress in a body, to find three planes at right angles to each other on which the stress is wholly normal, these being the principal stresses; and a number of propositions follow analogous to those for stresses all parallel to one plane. The discussions of these cases become very complex, and will not be treated here.

§ 295. **Some Applications.**—The following are some of the practical cases which require the theory of elasticity for their solution.

§ 296. **Combined Twisting and Bending.**—This is the case very generally in shafting, as the twist is necessary for the transmission of power, and the bending is due to the weight of the pulleys and shafting, and the pull of the belts, this being especially so when there are pulleys elsewhere than close to the hangers; also in overhanging shafts, in crank-shafts, etc.

Thus far we have no tests of shafting under combined twisting and bending, and therefore the methods used for calculating such shafts vary. With many it is the practice to compute their proper size from the twisting-moment only, but to make up for the bending by using a large factor of safety, the magnitude of this factor depending upon how much

the computer imagines the shaft will be weakened by the particular bending to which it is subjected.

With others it is customary to compute the deflections, under the greatest belt-pulls that can come upon it, by the principles of transverse stress, without any reference to the torsion, and to so determine it that the deflection computed in this way should not exceed  $\frac{1}{1200}$  or  $\frac{1}{1800}$  of the span.

On the other hand, Unwin and some others give the formulæ, which will be developed here for combined twisting and bending, as deduced by the theory of elasticity. This formula has not, as yet, been very extensively used; and its constants are taken from experiments on tension or torsion alone, and not on a combination of the two. It is to be hoped that we may some time have some experiments on such a combination. We will now proceed to deduce a formula for the greatest intensity of the stress at any point of the shaft.

For this purpose

Let  $M_1$  = bending-moment at any section.

$M_2$  = twisting-moment at the same section.

$I_1$  = moment of inertia about neutral axis for bending.

$I_2$  = moment of inertia about axis of shaft.

$r$  = distance from axis to outside fibre.

Then, if we denote by  $\sigma$  the greatest intensity of the stress due to bending, and by  $\tau$  the greatest intensity of the stress due to twisting, we have,

$$\sigma = \frac{M_1 r}{I_1}. \quad (1)$$

$$\tau = \frac{M_2 r}{I_2}. \quad (2)$$

For a circular or hollow circular shaft,

$$I_2 = 2I_1;$$

hence

$$\sigma = \frac{M_1 r}{I_1}. \quad (3)$$

$$\tau = \frac{M_2 r}{2I_1}. \quad (4)$$

Then, at a point at the outside of the shaft in the section under consideration, we shall have, —

1°. On a plane normal to the axis,

(a) a normal stress  $\sigma$ ,

(b) a shearing-stress  $\tau$ .

2°. On a plane in the direction of the axis,

(a) a normal stress  $\sigma$ .

(b) a shearing-stress  $\tau$ .

We thus have the case solved in Example I., § 290.

If, therefore, the greatest and least principal stresses be denoted by  $\sigma_1$  and  $\sigma_2$  respectively, we shall have

$$\sigma_1 = \frac{\sigma}{2} + \sqrt{\frac{\sigma^2}{4} + \tau^2}, \quad (5)$$

$$\sigma_2 = \frac{\sigma}{2} - \sqrt{\frac{\sigma^2}{4} + \tau^2}. \quad (6)$$

But, if  $\epsilon_1$  and  $\epsilon_2$  denote the strains in the directions of the principal stresses, we have

$$E\epsilon_1 = \sigma_1 - \frac{\sigma_2}{m}, \quad E\epsilon_2 = \sigma_2 - \frac{\sigma_1}{m};$$

Hence, substituting for  $\sigma_1$  and  $\sigma_2$  their values, we have

$$E\epsilon_1 = \frac{m-1}{2m}\sigma + \frac{m+1}{2m}\sqrt{\frac{\sigma^2}{4} + \tau^2}, \quad (7)$$

$$E\epsilon_2 = \frac{m-1}{2m}\sigma - \frac{m+1}{2m}\sqrt{\frac{\sigma^2}{4} + \tau^2}. \quad (8)$$

We then have, for the greatest stress on any fibre, the greater of the two quantities (7) and (8); and this should not at any section of the shaft exceed the working-strength of the material for tension.

The greater of the two is  $E_e$ ;: hence we should have, if  $f$  = greatest stress,

$$\frac{m-1}{2m}\sigma + \frac{m+1}{2m}\sqrt{\sigma^2 + 4\tau^2} = f. \quad (9)$$

If, now, we let  $m = 4$ , as is commonly done, we have

$$\frac{3}{8}\sigma + \frac{5}{8}\sqrt{\sigma^2 + 4\tau^2} = f, \quad (10)$$

this being the formula given by Grashof and others for combined twisting and bending.

On the other hand, Rankine puts the value of  $\sigma_1$  in (5) equal to  $f$ , and hence Rankine's formula is

$$\frac{\sigma}{2} + \frac{1}{2}\sqrt{\sigma^2 + 4\tau^2} = f. \quad (11)$$

This might be derived from (9) by making  $m = \infty$  instead of  $m = 4$ .

The formulæ developed above are applicable to any section.

#### APPLICATION TO CIRCULAR AND HOLLOW CIRCULAR SHAFTS.

Substituting for  $\sigma$  and  $\tau$  in (10) the values from (3) and (4), we should obtain

$$\frac{r}{I_1} \left\{ \frac{3}{8}M_1 + \frac{5}{8}\sqrt{M_1^2 + M_2^2} \right\} = f, \quad (12)$$

which is Grashof's formula, and is given by Unwin and others; and, substituting in (11) instead, we should have

$$\frac{r}{2I_1} (M_1 + \sqrt{M_1^2 + M_2^2}) = f. \quad (13)$$

Equation (12) is equivalent to the following rule:—

*Calculate the shaft as though it were subjected to a bending-moment*

$$M_o = \frac{3}{8}M_1 + \frac{3}{8}\sqrt{M_1^2 + M_2^2};$$

and equation (13) is equivalent to the following rule:—

*Calculate the shaft as though it were subjected to a bending-moment*

$$M_o = \frac{M_1}{2} + \frac{1}{2}\sqrt{M_1^2 + M_2^2}.$$

Now, if, as is usually the case, the section where the greatest bending-moment acts is also subjected to the greatest twisting-moment, it will only be necessary to put for  $M_1$  the greatest bending-moment, and for  $M_2$  the greatest twisting-moment.

§ 297. **Thick Hollow Cylinders subjected to a Uniform Normal Pressure.**—Let inside radius =  $r$ , outside radius =  $r_o$ , length of portion under consideration = unity, intensity of internal normal pressure =  $P$ , of external normal pressure =  $P_o$ .

1°. Divide the cylinder into a series of concentric rings; let radius of any ring be  $\rho$ , and thickness  $d\rho$ , these being the dimensions before the pressure is applied.

Let  $\rho$  become  $\rho + \xi$ , and  $d\rho$ ,  $d\rho + d\xi$ , after the pressure is applied.

Then at any point of this ring we shall have, for the strain in the radial direction,

$$\frac{d\xi}{d\rho}; \quad (1)$$

and, since the length of the ring before the application of the pressure is  $2\pi r$ , and after is  $2\pi(r + \xi)$ , hence the strain in a direction at right angles to the radius is

$$\frac{2\pi\xi}{2\pi\rho} = \frac{\xi}{\rho}. \quad (2)$$

2°. Impose, now, the conditions of equilibrium upon the forces exerted by the rest of the cylinder upon the upper half-ring. For this purpose let

$p$  = intensity of normal pressure on inside; i.e., at distance  $\rho$  from the axis.

$p + dp$  = intensity of normal pressure on outside; i.e., at distance  $\rho + d\rho$  from the axis.

Then we shall have for these forces, —

(a) Upward force due to internal pressure,

$$2p(\rho + \xi).$$

(b) Downward force due to external pressure,

$$2(p + dp)(\rho + \xi + d\rho + d\xi).$$

(c) Upward force at right angles to radius acting at division line between the two half-rings,

$$2t(d\rho + d\xi),$$

where  $t$  = intensity of hoop-tension per square unit; i.e., of tension in a circumferential direction. Then we have

$$2(p + dp)(\rho + \xi + d\rho + d\xi) - 2p(\rho + \xi) - 2t(d\rho + d\xi) = 0;$$

and, if this be reduced, and the terms

$$2pd\xi, \quad 2\xi dp, \quad 2dpd\rho, \quad 2dpd\xi, \quad \text{and} \quad 2td\xi$$

be omitted, all of which are very small compared with the remaining ones, we shall have

$$\frac{dp}{d\rho} + \frac{p - t}{\rho} = 0. \quad (3)$$

Now, the two stresses  $p$  and  $t$  are principal stresses, since

there are no shearing-stresses on these planes. Hence we have, from equations (1) and (2), § 282,

$$E \frac{d\xi}{d\rho} = p - \frac{t}{m}, \quad (4)$$

$$E \frac{\xi}{\rho} = t - \frac{p}{m}. \quad (5)$$

Now eliminate  $p$  and  $t$  between (3), (4), and (5), and obtain a differential equation between  $\rho$  and  $\xi$ .

Proceed as follows:—

From (4) and (5),

$$\begin{aligned} p &= \frac{Em^2}{m^2 - 1} \left( \frac{d\xi}{d\rho} + \frac{\xi}{m\rho} \right) \\ \therefore \frac{dp}{d\rho} &= \frac{Em^2}{m^2 - 1} \left( \frac{d^2\xi}{d\rho^2} + \frac{1}{m\rho} \frac{d\xi}{d\rho} - \frac{\xi}{m\rho^2} \right). \end{aligned}$$

From (4) and (5) also,

$$\frac{p - t}{\rho} = \frac{Em}{m + 1} \left( \frac{d\xi}{d\rho} - \frac{\xi}{\rho} \right).$$

Hence, substituting in (3), and reducing, we obtain

$$\frac{d^2\xi}{d\rho^2} + \frac{1}{\rho} \frac{d\xi}{d\rho} - \frac{\xi}{\rho^2} = 0 \quad (6)$$

$$\therefore \frac{d^2\xi}{d\rho^2} = - \left( \frac{1}{\rho} \frac{d\xi}{d\rho} - \frac{\xi}{\rho^2} \right) = - \frac{d \left( \frac{\xi}{\rho} \right)}{d\rho}.$$

Hence, by integration,

$$\frac{d\xi}{d\rho} = - \frac{\xi}{\rho} + 2a; \quad (7)$$

$2a$  being an arbitrary constant, to be determined from the conditions of the problem.

From (7) we obtain

$$\rho \frac{d\xi}{d\rho} + \xi = 2a\rho \quad \text{or} \quad \frac{d(\xi\rho)}{d\rho} = 2a\rho.$$

Hence, integrating, we have

$$\xi\rho = a\rho^2 + b, \quad (8)$$

$b$  being another arbitrary constant.

From (8) we obtain

$$\xi = a\rho + \frac{b}{\rho}, \quad (9)$$

which gives us, for the two strains,

$$\frac{d\xi}{d\rho} = a - \frac{b}{\rho^2}, \quad (10)$$

$$\frac{\xi}{\rho} = a + \frac{b}{\rho^2}, \quad (11)$$

Hence, substituting these values in (4) and (5), and solving for  $p$  and  $t$  successively, we obtain

$$p = \frac{Em}{m-1}a - \frac{Em}{m+1}\frac{b}{\rho^2}, \quad (12)$$

$$t = \frac{Em}{m-1}a + \frac{Em}{m+1}\frac{b}{\rho^2}. \quad (13)$$

Now, to determine  $a$  and  $b$ , we have the conditions, that, when  $\rho = r$ ,  $p = P$ , and when  $\rho = r_1$ ,  $p = -P_1$ .

Hence

$$P = \frac{Em}{m-1}a - \frac{Em}{m+1}\frac{b}{r^2}, \quad P_1 = \frac{Em}{m-1}a - \frac{Em}{m+1}\frac{b}{r_1^2},$$

$$\therefore a = \frac{m-1}{Em} \frac{P_1 r_1^2 - P r^2}{r_1^2 - r^2}, \quad b = \frac{m+1}{m} \frac{P_1 - P}{r_1^2 - r^2} r^2 r_1^2,$$

$$\therefore t = \frac{P_1 r_1^2 - P r^2}{r_1^2 - r^2} + \frac{1}{\rho^2} \frac{(P_1 - P) r^2 r_1^2}{r_1^2 - r^2}. \quad (14)$$

The greatest value of  $t$ , and hence the greatest intensity of the hoop-tension, occurs when  $\rho = r$ ; and hence we obtain

$$\text{Max } t = \frac{2P_1 r_1^2 - P(r_1^2 + r^2)}{r_1^2 - r^2}, \quad (15)$$

this value of  $t$  being negative when there is hoop-tension, because the signs were so chosen as to make  $t$  positive when denoting compression.

If  $P_1 = 0$ , i.e., if there is no external pressure, we have

$$\text{Max } t = -P \left( \frac{r_1^2 + r^2}{r_1^2 - r^2} \right); \quad (16)$$

and, according to Professor Rankine's method, we should determine the proper dimensions by keeping max  $t$  within the working-strength of the material.

On the other hand, if we decide that we will keep the value of  $E \left( \frac{\xi}{\rho} \right)$  within the working-strength, we shall find for this, when we make  $\rho = r$ ,

$$\text{Max } E \left( \frac{\xi}{\rho} \right) = \frac{[2P_1 r_1^2 - P(r_1^2 + r^2)] - \frac{1}{m} P(r_1^2 - r^2)}{(r_1^2 - r^2)}; \quad (17)$$

and, if  $m = 4$ ,

$$\text{Max } E \left( \frac{\xi}{\rho} \right) = \frac{2P_1 r_1^2 - P(r_1^2 + r^2) - \frac{1}{4} P(r_1^2 - r^2)}{(r_1^2 - r^2)}. \quad (18)$$

When  $P_1 = 0$ ,

$$\text{Max } E \left( \frac{\xi}{\rho} \right) = \frac{-P \left( \frac{5}{4} r_1^2 + \frac{3}{4} r^2 \right)}{r_1^2 - r^2}. \quad (19)$$

Practical cases of thick, hollow cylinders subjected to a uniform normal pressure occur in hydraulic presses and in ordnance.

§ 298. **Strength of Flat Plates.**—In this regard, the formulæ that will be deduced are those of Professor Grashof, the reasoning followed being substantially that given by him in his "Festigkeitslehre."

#### ROUND PLATES.

Let the curved line  $CA$  be a meridian curve of the middle layer of the plate after it is bent. Take the origin at  $O$ ; let axis  $OZ$  be vertical, and axis  $OX$  horizontal, and let the axis at right angles to  $ZOX$  be  $O\Phi$ , so that  $z$ ,  $x$ , and  $\phi$  are the coordinates of any point in the middle layer of the plate.

Let  $y$  denote the (vertical) distance of any horizontal layer from the middle layer of the plate.

Let  $R$  = radius of curvature of meridian line at any point  $(x, z, \phi)$ .

FIG. 303.

Let  $R_1$  = radius of curvature of section of middle layer normal to meridian line.

Then we should have, from the differential calculus,

$$R = -\frac{\frac{d^2 z}{dx^2}}{\left(1 + \left(\frac{dz}{dx}\right)^2\right)^{\frac{3}{2}}} = -\frac{d^2 z}{dx^2} \text{ nearly,}$$

$$R_1 = -\frac{1}{x} \frac{dz}{dx}.$$

Hence, reasoning in the same way as in the common theory of beams, we should have, for the strains of the layer whose dis-

tance from neutral layer is  $y$  at point  $(x, \phi)$ , provided there is no stress in the plane of the neutral layer,

$$\epsilon_x = \pm \frac{y}{R}, \quad \epsilon_\phi = \pm \frac{y}{R}.$$

When there is such a stress, let the strains due to that stress be  $\epsilon_{x_0}$  and  $\epsilon_{\phi_0}$ .

Then we shall have

$$\epsilon_x = \epsilon_{x_0} - y \frac{d^2 s}{dx^2}, \quad (1)$$

$$\epsilon_\phi = \epsilon_{\phi_0} - \frac{y}{x} \frac{ds}{dx}. \quad (2)$$

Hence, substituting in (1) and (2) of § 283, we have

$$\sigma_x = \frac{mE}{m^2 - 1} \left[ m\epsilon_{x_0} + \epsilon_{\phi_0} - y \left( m \frac{d^2 s}{dx^2} + \frac{1}{x} \frac{ds}{dx} \right) \right], \quad (3)$$

$$\sigma_\phi = \frac{mE}{m^2 - 1} \left[ \epsilon_{x_0} + m\epsilon_{\phi_0} - y \left( \frac{d^2 s}{dx^2} + \frac{m}{x} \frac{ds}{dx} \right) \right]. \quad (4)$$

Now let us suppose the plate to be subjected, before loading, to a uniform pull in its own plane, and normal to its circumference; and let the intensity of this pull be  $p_1$ . Then

$$\sigma_{x_0} = \sigma_{\phi_0} = p_1;$$

and hence, from (1) and (2), we have

$$\epsilon_{x_0} = \epsilon_{\phi_0} = \frac{p_1(m-1)}{mE}. \quad (5)$$

Therefore, substituting in (3) and (4), and reducing,

$$\sigma_x = p_1 - \frac{mEy}{m^2 - 1} \left( m \frac{d^2 s}{dx^2} + \frac{1}{x} \frac{ds}{dx} \right), \quad (6)$$

$$\sigma_\phi = p_1 - \frac{mEy}{m^2 - 1} \left( \frac{d^2 s}{dx^2} + \frac{m}{x} \frac{ds}{dx} \right). \quad (7)$$

These equations express the stresses in terms of the co-ordinates of the points.

Now impose the conditions of equilibrium upon the forces acting on any half-ring of thickness  $dx = d\phi$ .

These forces are —

1°. Force exerted upon it by the outer part of the plate,

$$\{2x\sigma_x + 2d(x\sigma_x)\}ds.$$

FIG. 304.

2°. Force exerted by the inner part of the plate,

$$-2x\sigma_x ds.$$

3°. Force exerted upon it by the other half-ring,

$$-2\sigma_\phi dx ds.$$

4°. Force exerted by resistance to shear on top and bottom,

$$\{(\tau + d\tau) - \tau\}2x dx.$$

Hence, equating to zero the algebraic sum of these, and reducing, we obtain

$$\frac{d\tau}{ds} = \frac{d\tau}{dy} = \frac{\sigma_\phi}{x} - \frac{1}{x} \frac{d(x\sigma_x)}{dx}. \quad (8)$$

Now substitute for  $\sigma_x$  and  $\sigma_\phi$  their values, and reduce, and we have

$$\frac{d\tau}{dy} = \frac{m^2 Ey^2}{m^2 - 1} \left( \frac{d^3 s}{dx^3} + \frac{1}{x} \frac{d^2 s}{dx^2} - \frac{1}{x^2} \frac{ds}{dx} \right). \quad (9)$$

Integrate with regard to  $y$ , and we have, since the quantity in brackets is not a function of  $y$ ,

$$\tau = \frac{m^2 Ey^2}{2(m^2 - 1)} \left( \frac{d^3 s}{dx^3} + \frac{1}{x} \frac{d^2 s}{dx^2} + \frac{1}{x^2} \frac{ds}{dx} \right) + c.$$

But, when  $y = \frac{h}{2}$  ( $h$  being the thickness of the plate),  $\tau = 0$ , since there is no shearing-force at top or bottom ;

$$\therefore c = -\frac{m^2 E h^2}{8(m^2 - 1)} \left( \frac{d^3 z}{dx^3} + \frac{1}{x} \frac{d^2 z}{dx^2} - \frac{1}{x^2} \frac{dz}{dx} \right)$$

$$\therefore \tau = \frac{m^2 E (h^2 - 4y^2)}{8(m^2 - 1)} \left( \frac{d^3 z}{dx^3} + \frac{1}{x} \frac{d^2 z}{dx^2} - \frac{1}{x^2} \frac{dz}{dx} \right). \quad (10)$$

This gives us the intensity of the shearing-stress at any point  $(x, s)$  at distance  $y$  from middle layer; and this is the intensity of the shear at that point between two horizontal layers, and hence also along a vertical plane through the point  $(x, s)$ .

Now let us take the case of a centre load  $P$  combined with a distributed load  $p$  per unit of area. Then shearing-force at distance  $x$  from centre =

$$\pi x^2 p + P,$$

this tending to shear out a circular piece of radius  $x$ . Hence we must have this balanced by the whole shearing resistance on the surface subjected to shear ;

$$\therefore 2\pi x \int_{-\frac{h}{2}}^{\frac{h}{2}} \tau dy = \pi x^2 p + P$$

$$\therefore \int_{-\frac{h}{2}}^{\frac{h}{2}} \tau dy = \frac{1}{2} \left( px + \frac{P}{\pi x} \right). \quad (11)$$

Now substitute the value of  $\tau$  from equation (9), integrate, and reduce, and we obtain

$$\frac{d^3 z}{dx^3} + \frac{1}{x} \frac{d^2 z}{dx^2} - \frac{1}{x^2} \frac{dz}{dx} = -\frac{6(m^2 - 1)}{m^2 E h^3} \left( px + \frac{P}{\pi x} \right). \quad (12)$$

Hence, for the intensity of the shearing-force, we have

$$\tau = \frac{3}{4} \frac{h^2 - 4y^2}{h^3} \left( px + \frac{P}{\pi x} \right). \quad (13)$$

This gives the intensity of the shearing-force at any point of the plate.

Next, to find its deflection, or the equation of the meridian line, we have, from (12),

$$\frac{d}{dx} \left( \frac{d^2 z}{dx^2} + \frac{1}{x} \frac{dz}{dx} \right) = - \frac{6(m^2 - 1)}{m^2 E h^3} \left( px + \frac{P}{\pi x} \right)$$

$$\therefore \frac{d^2 z}{dx^2} + \frac{1}{x} \frac{dz}{dx} = - \frac{6(m^2 - 1)}{m^2 E h^3} p \frac{x^2}{2} - \frac{6(m^2 - 1)}{m^2 E h^3} \frac{P}{\pi} \log_e x + c$$

$$\therefore x \frac{d^2 z}{dx^2} + \frac{dz}{dx} = - \frac{6(m^2 - 1)}{m^2 E h^3} p \frac{x^3}{2} - \frac{6(m^2 - 1)}{m^2 E h^3} \frac{P}{\pi} x \log_e x + cx.$$

But

$$x \frac{d^2 z}{dx^2} + \frac{dz}{dx} = \frac{d}{dx} \left( x \frac{dz}{dx} \right);$$

hence, integrating, we have

$$\begin{aligned} x \frac{dz}{dx} &= - \frac{6(m^2 - 1)}{m^2 E h^3} p \frac{x^4}{8} \\ &\quad - \frac{6(m^2 - 1)}{m^2 E h^3} \frac{P}{\pi} \frac{x^2}{2} \log_e x + \frac{6(m^2 - 1)}{m^2 E h^3} \frac{x^2}{4} + \frac{cx^2}{2} + d. \end{aligned} \quad (14)$$

Hence, dividing through by  $x$ , and integrating,

$$\begin{aligned} z &= - \frac{6(m^2 - 1)}{m^2 E h^3} p \frac{x^4}{4} \\ &\quad - \frac{6(m^2 - 1)}{m^2 E h^3} \frac{P}{\pi} \frac{x^2}{4} (\log_e x - 1) + \frac{cx^2}{4} + d \log_e x + e; \end{aligned} \quad (15)$$

and this is the meridian line of the surface, the constants  $c$ ,  $d$ , and  $e$  being as yet undetermined.

This is as far as we can proceed before taking up special cases.

(a) *Full Plate.*—When the plate is full, the slope becomes zero, for  $x = 0$ ; therefore (14) gives us

$$d = 0,$$

and in this case (15) becomes

$$s = -\frac{6(m^2 - 1)}{m^2 E h^3} p \frac{x^4}{4} - \frac{6(m^2 - 1)}{m^2 E h^3} \frac{P x^2}{\pi 4} (\log_e x - 1) + \frac{c x^2}{4} + c. \quad (16)$$

And, substituting for  $s$ ,  $\frac{ds}{dx}$  and  $\frac{d^2s}{dx^2}$ , their values in (1) and (2), we obtain

$$E \epsilon_x = \frac{m - 1}{m} \sigma_{x_0} + \left( \frac{3}{8} \frac{6(m^2 - 1)}{m^2 E h^3} p - \frac{c}{2} \right) y, \quad (17)$$

$$E \epsilon_y = \frac{m - 1}{m} \sigma_{x_0} + \left( \frac{1}{8} \frac{6(m^2 - 1)}{m^2 E h^3} p - \frac{c}{2} \right) y; \quad (18)$$

and (13) gives

$$\tau = \frac{3}{4} \frac{h^2 - 4y^2}{h^3} p x. \quad (19)$$

(a) *Uniformly Loaded, no Centre Load.*— $P = 0$ ;

$$\therefore s = -\frac{6(m^2 - 1)}{m^2 E h^3} p \frac{x^4}{4} + \frac{c x^2}{4} + c. \quad (20)$$

But when  $x = r$ ,  $s = 0$ ;

$$\therefore c = \frac{6(m^2 - 1)}{m^2 E h^3} \frac{r^4}{32} - \frac{c r^2}{4}$$

$$\therefore s = \left( \frac{6(m^2 - 1)}{m^2 E h^3} p \frac{x^2 + r^2}{8} - c \right) \left( \frac{r^2 - x^2}{4} \right). \quad (21)$$

( $\beta$ ) *Supported all around.*—When  $x = r$ ,  $\sigma_x = \sigma_{x_0} = p$ , for all values of  $y$ : therefore, from (6),

$$m \left( \frac{d^2 z}{dx^2} \right)_r + \frac{1}{r} \left( \frac{dz}{dx} \right)_r = 0;$$

and, substituting the values of  $\frac{dz}{dx}$  and  $\frac{d^2 z}{dx^2}$  as determined by differentiating (21), we have, after reducing,

$$c = \frac{3}{2} \frac{(m-1)(3m+1)}{m^2} \frac{pr^2}{Eh^3}.$$

Hence equation of meridian line is

$$z = \frac{3}{16} \frac{m^2 - 1}{m^2} \frac{p}{Eh^3} \left\{ \frac{5m+1}{m+1} r^2 - x^2 \right\} (r^2 - x^2). \quad (22)$$

Hence we have maximum deflection by making  $x = 0$ ;

$$\therefore z_0 = \frac{3}{16} \frac{(m-1)(5m+1)}{m^2} \frac{pr^4}{Eh^3}. \quad (23)$$

And, substituting in (17) and (18), we obtain, after reduction,

$$E\epsilon_x = \frac{m-1}{m} p_1 + \frac{3}{4} \frac{m^2 - 1}{m^2} \frac{p}{h^3} \left\{ \frac{3m+1}{m+1} r^2 - 3x^2 \right\} y, \quad (24)$$

$$E\epsilon_y = \frac{m-1}{m} p_1 + \frac{3}{4} \frac{m^2 - 1}{m^2} \frac{p}{h^3} \left\{ \frac{3m+1}{m+1} r^2 - x^2 \right\} y. \quad (25)$$

But, in a plate supported all around,  $p_1 = 0$ ; and then the maximum value of either one occurs when  $y = \frac{h}{2}$ , and hence

$$E\epsilon_0 = \frac{3}{8} \frac{(m-1)(3m+1)}{m^2} \frac{pr^2}{h^2}. \quad (26)$$

On the other hand,  $\tau$  becomes greatest when  $x = r$  and  $y = 0$ . Hence

$$\text{Max } E\tau = \frac{3}{4} \frac{r}{h} p;$$

and, if  $\epsilon$ , represent the maximum strain due to this shearing-force, we have

$$\text{Max } (E\epsilon) = \left( \frac{m+1}{m} \right) (\text{max } E\tau) = \frac{3}{4} \frac{m+1}{m} \frac{r}{h} p. \quad (27)$$

RESULTING FORMULÆ FOR PLATE SUPPORTED ALL ROUND.

$$\text{Max } E\epsilon_0 = \frac{3}{8} \frac{(m-1)(3m+1)}{m^2} \frac{r^2}{h^2} p \quad \text{or} \quad \frac{3}{4} \frac{m+1}{m} \frac{r}{h} p,$$

whichever is greatest.

$$z_0 = \frac{3}{16} \frac{(m-1)(5m+1)}{m^2} \frac{pr^4}{Eh^3}.$$

PLATE FIXED AT ENDS.

Equation (20) applies to this case also.

Now, when  $x = r$ ,  $\frac{dz}{dx} = 0$ ;

$$\therefore c = \frac{3}{2} \frac{m^2 - 1}{m^2 E h^3} p r^2$$

$$\therefore z = \frac{3}{16} \frac{m^2 - 1}{m^2} \frac{p}{E h^3} (r^2 - x^2)^2. \quad (28)$$

Hence greatest deflection is

$$z_0 = \frac{3}{16} \frac{m^2 - 1}{m^2} \frac{pr^4}{Eh^3},$$

and

$$E\epsilon_x = \frac{m-1}{m}p_1 + \frac{3}{4} \frac{m^2-1}{m^2} \frac{p}{h^3} (r^2 - 3x^2)y, \quad (29)$$

$$E\epsilon_y = \frac{m-1}{m}p_1 + \frac{3}{4} \frac{m^2-1}{m^2} \frac{p}{h^3} (r^2 - x^2)y. \quad (30)$$

When  $p_1$  is positive or zero, then  $E\epsilon_x$  is maximum for  $x=0$ ,  $y=\frac{h}{2}$ , and for  $x=r$ ,  $y=-\frac{h}{2}$ ; and  $E\epsilon_y$  is maximum for  $x=0$ ,  $y=\frac{h}{2}$ : and the maximum value of  $E\epsilon_y$  is equal to first maximum of  $E\epsilon_x$ . We have

$$\text{First max } E\epsilon_x = \frac{m-1}{m}p_1 + \frac{3}{8} \frac{m^2-1}{m^2} \frac{r^2}{h^2}p, \quad (31)$$

$$\text{Second max } E\epsilon_x = \frac{m-1}{m}p_1 + \frac{3}{4} \frac{m^2-1}{m^2} \frac{r^2}{h^2}p. \quad (32)$$

Hence the second is the real maximum.

#### RESULTING FORMULÆ FOR PLATES FIXED AT THE ENDS.

$$\text{Max } E\epsilon_0 = \frac{m-1}{m}p_1 + \frac{3}{4} \frac{m^2-1}{m^2} \frac{r^2}{h^2}p,$$

$$s_0 = \frac{3}{16} \frac{m^2-1}{m^2} \frac{pr^4}{Eh^3}.$$

For  $p_1 = 0$ ,

$$\text{Max } E\epsilon_0 = \frac{3}{4} \frac{m^2-1}{m^2} \frac{r^2}{h^2}p.$$

§ 299. **Thickness of Plates.** — Grashof advises the use of 3 as value of  $m$ . If this be adopted, we should have, for the proper thickness of round plates,

$$\text{Supported.} \\ h = r\sqrt{\frac{5p}{6f}}$$

$$\text{Fixed.} \\ h = r\sqrt{\frac{2p}{3f}}$$

where  $h$  = thickness,  $r$  = radius,  $p$  = pressure per square inch, and  $f$  = working-strength per square inch. If, now, we use a factor of safety 8, and use as tensile strength of cast-iron 20000, of wrought-iron, 48000, and of steel 80000, we should have :—

|                 | Supported.               | Fixed.                   |
|-----------------|--------------------------|--------------------------|
| Cast-iron . . . | $h = 0.0182570r\sqrt{p}$ | $h = 0.0163300r\sqrt{p}$ |
| Wrought-iron .  | $h = 0.0117850r\sqrt{p}$ | $h = 0.0105410r\sqrt{p}$ |
| Steel . . . .   | $h = 0.0091287r\sqrt{p}$ | $h = 0.0081649r\sqrt{p}$ |

§ 300. **Rectangular Plates.**—Refer the plate to rectangular axes, as before,  $OZ$ ,  $OX$ ,  $O\Phi$ ; the origin being at the middle of its middle layer.

Let  $y$  = distance of any point in the plate from the middle layer.

Let  $\rho_x$  be the radius of curvature of a normal section parallel to  $OX$  at the point  $(x, z, \phi)$ .

Let  $\rho_\phi$  be the radius of curvature of a normal section parallel to  $O\Phi$  at the point  $(x, z, \phi)$ .

Then we shall have, by the principles of the common theory of beams,

$$\epsilon_x = \epsilon_{x_0} \pm \frac{y}{\rho_x}, \quad \epsilon_\phi = \epsilon_{\phi_0} \pm \frac{y}{\rho_\phi}$$

where  $\epsilon_{x_0}$  and  $\epsilon_{\phi_0}$  are the strains of the middle layer in the directions  $OX$  and  $O\Phi$  respectively.

Moreover, from the Differential Calculus, we have

$$\rho_x = \frac{\sqrt{1 + \left(\frac{dz}{dx}\right)^2 + \left(\frac{dz}{d\phi}\right)^2}}{\frac{d^2z}{dx^2} \cos^2 \lambda + 2 \frac{d^2z}{dx d\phi} \cos \lambda \cos \mu + \frac{d^2z}{d\phi^2} \cos^2 \mu}$$

where  $\lambda$  = angle between normal and  $z$  axis, and  $\mu$  = angle between normal and  $x$  axis. But  $\frac{dz}{dx}$  and  $\frac{dz}{d\phi}$  being the slopes, and hence small, we shall have nearly

$$\cos \lambda = 1, \quad \cos \mu = 0,$$

$$\frac{1}{\rho_x} = \mp \frac{d^2 z}{dx^2}, \quad \frac{1}{\rho_\phi} = \mp \frac{d^2 z}{d\phi^2}$$

$$\therefore \epsilon_x = \epsilon_{x_0} - y \frac{d^2 z}{dx^2}, \quad (1)$$

$$\epsilon_\phi = \epsilon_{\phi_0} - y \frac{d^2 z}{d\phi^2}. \quad (2)$$

Hence (1) and (2) of § 283 give us

$$\sigma_x = \frac{mE}{m^2 - 1} (m\epsilon_{x_0} + \epsilon_{\phi_0}) - y \frac{mE}{m^2 - 1} \left\{ m \frac{d^2 z}{dx^2} + \frac{d^2 z}{d\phi^2} \right\},$$

$$\sigma_\phi = \frac{mE}{m^2 - 1} (\epsilon_{x_0} + m\epsilon_{\phi_0}) - y \frac{mE}{m^2 - 1} \left\{ \frac{d^2 z}{dx^2} + m \frac{d^2 z}{d\phi^2} \right\}.$$

And, if  $\sigma_{x_0}$ ,  $\sigma_{\phi_0}$  denote the stresses in the middle layer, we shall have, since

$$\sigma_{x_0} = \frac{mE}{m^2 - 1} (m\epsilon_{x_0} + \epsilon_{\phi_0}), \quad \sigma_{\phi_0} = \frac{mE}{m^2 - 1} (\epsilon_{x_0} + m\epsilon_{\phi_0}),$$

$$\sigma_x = \sigma_{x_0} - \frac{m^2 E}{m^2 - 1} y \left\{ \frac{d^2 z}{dx^2} + \frac{1}{m} \frac{d^2 z}{d\phi^2} \right\}, \quad (3)$$

$$\sigma_y = \sigma_{y_0} - \frac{m^2 E}{m^2 - 1} y \left\{ \frac{1}{m} \frac{d^2 z}{dx^2} + \frac{d^2 z}{d\phi^2} \right\}. \quad (4)$$

Now, if  $\xi$  and  $\eta$  denote the increments in  $x$  and  $\phi$  respectively due to the load, we shall have

$$\xi = \int_0^x \epsilon_x dx = x\epsilon_{x_0} - y \frac{dz}{dx} \quad \therefore \frac{d\xi}{d\phi} = -y \frac{d^2 z}{dx d\phi},$$

$$\eta = \int_0^\phi \epsilon_\phi d\phi = \phi\epsilon_{\phi_0} - y \frac{dz}{d\phi} \quad \therefore \frac{d\eta}{dx} = -y \frac{d^2 z}{dx d\phi}.$$

But

$$\tau_{x\phi} = G\gamma_{x\phi} = G\left(\frac{d\xi}{d\phi} + \frac{d\eta}{dx}\right);$$

hence

$$\tau_{x\phi} = -2Gy \frac{d^2 z}{dx d\phi}. \quad (5)$$

Equations (3), (4), and (5) are the expressions giving the stresses on two planes at right angles to each other, parallel to  $OX$  and  $O\phi$  respectively. Hence we have a case of stress on two planes at right angles to each other, and we are to find the principal stresses: we thus have —

1°. Normal stress on  $x$  plane,  $\sigma_x$

2°. Shearing-stress on  $x$  plane,  $\tau_{x\phi}$

3°. Normal stress on  $\phi$  plane,  $\sigma_\phi$

4°. Shearing-stress on  $\phi$  plane,  $\tau_\phi$

Hence, if we denote by  $\sigma_1$  and  $\sigma_2$  the maximum and minimum principal stress, we have (§ 290)

$$\sigma_1 = \frac{1}{2}(\sigma_x + \sigma_\phi) + \frac{1}{2}\sqrt{(\sigma_x + \sigma_\phi)^2 + 4\tau_{x\phi}^2}, \quad (6)$$

$$\sigma_2 = \frac{1}{2}(\sigma_x + \sigma_\phi) - \frac{1}{2}\sqrt{(\sigma_x + \sigma_\phi)^2 + 4\tau_{x\phi}^2}; \quad (7)$$

and hence, if  $\epsilon_1$  and  $\epsilon_2$  denote the strains in the directions of the principal stresses,

$$E\epsilon_1 = \sigma_1 - \frac{\sigma_2}{m} = \frac{m-1}{2m}(\sigma_x + \sigma_\phi) + \frac{m+1}{2m}\sqrt{(\sigma_x + \sigma_\phi)^2 + 4\tau_{x\phi}^2}, \quad (8)$$

$$E\epsilon_2 = \sigma_2 - \frac{\sigma_1}{m} = \frac{m-1}{2m}(\sigma_x + \sigma_\phi) - \frac{m+1}{2m}\sqrt{(\sigma_x + \sigma_\phi)^2 + 4\tau_{x\phi}^2}; \quad (9)$$

and for the strain  $\epsilon_z$ , parallel to  $OZ$ , we have

$$E\epsilon_z = -\frac{\sigma_x + \sigma_\phi}{m}. \quad (10)$$

In order to use (8), (9), and (10), however, we must know  $\sigma_x$ ,  $\sigma_\phi$ , and  $\tau_{x\phi}$ ; and for this purpose we must know the equation of the middle layer after bending. For this purpose, apply the equations (1), (2), (3), of § 281 to any particle  $dx d\phi dz$  in the interior of the body. We have then,  $X = Y = Z = 0$ . Therefore

$$\frac{d\sigma_x}{dx} + \frac{d\tau_{xz}}{dy} + \frac{d\tau_{x\phi}}{d\phi} = 0 \quad \therefore \quad \frac{d\tau_{xz}}{dy} = -\left(\frac{d\sigma_x}{dx} + \frac{d\tau_{x\phi}}{d\phi}\right),$$

$$\frac{d\sigma_\phi}{d\phi} + \frac{d\tau_{x\phi}}{dx} + \frac{d\tau_{\phi z}}{dy} = 0 \quad \therefore \quad \frac{d\tau_{\phi z}}{dy} = -\left(\frac{d\sigma_\phi}{d\phi} + \frac{d\tau_{x\phi}}{dx}\right),$$

$$\frac{d\sigma_z}{dy} + \frac{d\tau_{\phi z}}{d\phi} + \frac{d\tau_{xz}}{dx} = 0.$$

Therefore, making use of (3), (4), and (5) with the above conditions, we deduce

$$\frac{d\sigma_x}{dx} = -\frac{m^2 Ey}{m^2 - 1} \left( \frac{d^3 z}{dx^3} + \frac{1}{m} \frac{d^3 z}{dx d\phi^2} \right), \quad (11)$$

$$\frac{d\sigma_\phi}{d\phi} = \frac{m^2 Ev}{m^2 - 1} \left( \frac{d^3 z}{d\phi^3} + \frac{1}{m} \frac{d^3 z}{dx^2 d\phi} \right), \quad (12)$$

$$\frac{d\tau_{xy}}{dx} = -\frac{mEy}{m+1} \frac{d^3 z}{dx^2 d\phi}, \quad (13)$$

$$\frac{d\tau_{x\phi}}{d\phi} = -\frac{mEy}{m+1} \frac{d^3 z}{dx d\phi^2}, \quad (14)$$

$$\frac{d\tau_{xz}}{dy} = \frac{m^2 Ev}{m^2 - 1} \left( \frac{d^3 z}{dx^3} + \frac{d^3 z}{dx d\phi^2} \right), \quad (15)$$

$$\frac{d\tau_{\phi z}}{dy} = \frac{m^2 Ev}{m^2 - 1} \left( \frac{d^3 z}{dy^3} + \frac{d^3 z}{dx^2 dy} \right) \quad (16)$$

Hence, by integrating (15) and (16), we have

$$\tau_{xz} = \frac{m^2 E v^2}{2(m^2 - 1)} \left( \frac{d^3 z}{dx^3} + \frac{d^3 z}{dx d\phi^2} \right) + c_1,$$

$$\tau_{\phi z} = \frac{m^2 E v^2}{2(m^2 - 1)} \left( \frac{d^3 z}{d\phi^3} + \frac{d^3 z}{dx^2 d\phi} \right) + c_2.$$

But when  $v = \frac{h}{2}$ ,  $\tau_{\phi z} = \tau_{xz} = 0$ ;

$$\therefore c_1 = -\frac{m^2 E h^2}{8(m^2 - 1)} \left( \frac{d^3 z}{dx^3} + \frac{d^3 z}{dx d\phi^2} \right)$$

and

$$c_2 = -\frac{m^2 E h^2}{8(m^2 - 1)} \left( \frac{d^3 z}{d\phi^3} + \frac{d^3 z}{dx^2 d\phi} \right)$$

$$\therefore \tau_{\phi z} = \frac{m^2 E}{m^2 - 1} \left( \frac{d^3 z}{dx^2 d\phi} + \frac{d^3 z}{d\phi^3} \right) \left( \frac{v^2}{2} - \frac{h^2}{8} \right)$$

and

$$\tau_{xz} = \frac{m^2 E}{m^2 - 1} \left( \frac{d^3 z}{dx^3} + \frac{d^3 z}{dx d\phi^2} \right) \left( \frac{v^2}{2} - \frac{h^2}{8} \right).$$

Hence

$$\frac{d\tau_{\phi z}}{d\phi} = \frac{m^2 E}{m^2 - 1} \left( \frac{d^4 z}{dx^2 d\phi^2} + \frac{d^4 z}{d\phi^4} \right) \left( \frac{v^2}{2} - \frac{h^2}{8} \right),$$

$$\frac{d\tau_{xz}}{dx} = \frac{m^2 E}{m^2 - 1} \left( \frac{d^4 z}{dx^4} + \frac{d^4 z}{dx^2 d\phi^2} \right) \left( \frac{v^2}{2} - \frac{h^2}{8} \right).$$

Now we have  $\sigma_z = p$ , where  $p$  is the intensity of the load; therefore the third equation gives us, on integrating between the limits  $\frac{h}{2}$  and  $-\frac{h}{2}$ ,

$$\sigma_z + \int_{-\frac{h}{2}}^{\frac{h}{2}} \frac{d\tau_{\phi z}}{d\phi} dy + \int_{-\frac{h}{2}}^{\frac{h}{2}} \frac{d\tau_{xz}}{dx} dy = 0$$

$$\therefore p + \int_{-\frac{h}{2}}^{\frac{h}{2}} \frac{d\tau_{\phi z}}{d\phi} dy + \int_{-\frac{h}{2}}^{\frac{h}{2}} \frac{d\tau_{xz}}{dx} dy = 0$$

$$\therefore p + \frac{m^2 E}{m^2 - 1} \left\{ \left( \frac{v^3}{6} - \frac{h^2 v}{8} \right) \left( \frac{d^4 z}{dx^4} + 2 \frac{d^4 z}{dx^2 d\phi^2} + \frac{d^4 z}{d\phi^4} \right)^{\frac{h}{2}} \right\} = 0$$

$$\therefore p + \frac{m^2 E}{m^2 - 1} \left( \frac{d^4 z}{dx^4} + 2 \frac{d^4 z}{dx^2 d\phi^2} + \frac{d^4 z}{d\phi^4} \right) \left( \frac{h^3}{24} - \frac{h^3}{8} \right) = 0$$

$$\therefore \frac{d^4 z}{dx^4} + 2 \frac{d^4 z}{dx^2 d\phi^2} + \frac{d^4 z}{d\phi^4} = \frac{12(m^2 - 1)p}{m^2 E h^3}; \quad (17)$$

and this is the differential equation of the surface, and should be integrated in each special case.

INDEFINITE PLATES WHICH ARE FIRMLY HELD AT A SYSTEM OF POINTS DIVIDING THEM INTO RECTANGULAR PANELS.

Let the sides of the panels be  $2a$  and  $2b$ . Assume the origin at the middle of the panel, the axis of  $x$  being parallel to  $2a$ , and the axis of  $y$  parallel to  $2b$ . We shall in this case have the following conditions; viz.,—

(a)  $\frac{dz}{dx} = 0$  for  $x = \pm a$  and all values of  $\phi$ .

(b)  $\frac{dz}{d\phi} = 0$  for  $\phi = \pm b$  and all values of  $x$ .

(c)  $z = 0$  when  $x = \pm a, \phi = \pm b$ .

(d) If we develop the value of  $z$  in powers of  $x$  and  $\phi$ , there must enter only even powers of  $x$  and  $\phi$ , since the value of  $z$  remains the same when we put  $-x$  for  $x$ , or  $-\phi$  for  $\phi$ .

Now, if we write

$$z = A + Bx^2 + C\phi^2 + Dx^2\phi^2 + Ex^4 + F\phi^4 \\ + Gx^6 + Hx^4\phi^2 + Kx^2\phi^4 + L\phi^6 + Mx^8, \text{ etc.,}$$

the above conditions will be fulfilled:—

1°. By making all the co-efficients after the fourth, each zero.

2°. By making  $D = 0$ , therefore writing

$$z = A + Bx^2 + C\phi^2 + Ex^4 + F\phi^4.$$

Now

$$\frac{dz}{dx} = 2Bx + 4Ex^3, \quad \frac{dz}{d\phi} = 2C\phi + 4F\phi^3,$$

$$\therefore 2Ba + 4Ea^3 = 0, \quad 2Cb + 4Fb^3 = 0,$$

and

$$0 = A + Ba^2 + Cb^2 + Ea^4 + Fb^4$$

$$\therefore B = -2Ea^2, \quad C = -2Fb^2,$$

$$\therefore A = 2Ea^4 + 2Fb^4 - Ea^4 - Fb^4 = Ea^4 + Fb^4.$$

Hence the equation becomes

$$z = Ea^4 + Fb^4 - 2Ea^2x^2 - 2Fb^2\phi^2 + Ex^4 + F\phi^4 \\ = E(a^2 - x^2)^2 + F(b^2 - \phi^2)^2$$

$$\therefore \frac{dz}{dx} = -4Ex(a^2 - x^2) = 4Ex^3 - 4Ea^2x$$

$$\therefore \frac{d^2z}{dx^2} = 12Ex^2 - 4Ea^2,$$

also

$$\frac{dz}{d\phi} = -4F\phi(b^2 - \phi^2) = 4F\phi^3 - 4Fb^2\phi$$

$$\therefore \frac{d^2z}{d\phi^2} = 12F\phi^2 - 4Fb^2,$$

$$\frac{d^3z}{dx^2d\phi} = 0 \quad \therefore \frac{d^4z}{dx^2d\phi^2} = 0, \quad \frac{d^3z}{dx d\phi^2} = 0, \quad \frac{d^4z}{dx^2d\phi^3} = 0,$$

$$\frac{d^3z}{dx^3} = 24Ex, \quad \frac{d^3z}{d\phi^3} = 24F\phi, \quad \frac{d^4z}{dx^4} = 24E, \quad \frac{d^4z}{d\phi^4} = 24F$$

$$\therefore 24(E + F) = \frac{12(m^2 - 1)\rho}{m^2 E h^3} \quad \therefore E + F = \frac{(m^2 - 1)\rho}{2m^2 E h^3}.$$

Hence equation of the middle layer is

$$z = E(a^2 - x^2)^2 + F(b^2 - \phi^2)^2, \text{ where } E + F = \frac{(m^2 - 1)\rho}{2m^2 E h^3}. \quad (18)$$

Now, in the case of an ordinary beam fixed at both ends, and loaded uniformly with  $p$  lbs. per unit of area, if  $b$  is the breadth, we have :—

1°. The points of inflection are at a distance from the middle equal to  $\frac{a}{\sqrt{3}}$ , where  $a$  is the half-span ; and

2°. The bending-moment at a section at a distance  $x$  from the middle is  $\frac{pb}{2}\left(\frac{a^2}{3} - x^2\right)$  when  $x < \frac{a}{\sqrt{3}}$ , and  $\frac{pb}{2}\left(x^2 - \frac{a^2}{3}\right)$  when  $x > \frac{a}{\sqrt{3}}$ ; therefore the value of  $s$  is found from the formula

$$s = \frac{1}{EI} \int_0^x \int_0^x M dx^2 = \frac{6p}{Eh^3} \int_0^x \int_0^x \left(x^2 - \frac{a^2}{3}\right) dx^2$$

or

$$\frac{6p}{Eh^3} \int_0^x \int_0^x \left(\frac{a^2}{3} - x^2\right) dx^2.$$

Either one, when integrated, gives for  $s$  the value

$$s = \frac{p}{2Eh^3} (a^2 - x^2)^2.$$

Hence in the flat plate, if  $b = 0$ , the values of  $E$  and  $F$  must be such that the formula shall reduce to  $s = \frac{p}{2Eh^3} (a^2 - x^2)^2$  when  $b = 0$ . Now, it does reduce to  $s = E(a^2 - x^2)^2$ . Therefore  $E$  must be such a function of  $a$  and  $b$ , that, when  $b = 0$ , it shall reduce to  $\frac{p}{2Eh^3}$ . So likewise  $F$  must be such a function of  $a$  and  $b$ , that, when  $a = 0$ , it shall reduce to  $\frac{p}{2Eh^3}$ . Suppose, then, we put

$$E = \frac{p}{2Eh^3} + b^m c \quad \text{and} \quad F = \frac{p}{2Eh^3} + a^n c,$$

since these functions fulfil the above conditions.

Now we have

$$E + F = \frac{(m^2 - 1)\rho}{2m^2 E h^3}$$

$$\therefore \frac{\rho}{2 E h^3} + c(a^n + b^n) = \frac{(m^2 - 1)\rho}{2m^2 E h^3}$$

$$\therefore (a^n + b^n)c = -\frac{(m^2 + 1)\rho}{2m^2 E h^3}$$

$$\therefore c = -\frac{(m^2 + 1)\rho}{2m^2 E h^3(a^n + b^n)}$$

$$\therefore E\epsilon_x = \sigma_{x_0} - \frac{1}{m}\sigma_{\phi_0} + yE\frac{d^2g}{dx^2},$$

$$E\epsilon_\phi = \sigma_{\phi_0} - \frac{1}{m}\sigma_{x_0} - yE\frac{d^2g}{d\phi^2}.$$

Hence, substituting for  $\frac{d^2g}{dx^2}$  and  $\frac{d^2g}{d\phi^2}$  their values, and observing that

$$\epsilon_x \text{ is greatest for } x = \pm a, y = \pm \frac{h}{2},$$

$$\epsilon_\phi \text{ is greatest for } \phi = \pm b, y = \pm \frac{h}{2},$$

we obtain

$$\max(E\epsilon_x) = \sigma_{x_0} - \frac{1}{m}\sigma_{\phi_0} \pm 2 \frac{a^n - \frac{1}{m^2}b^n}{a^n + b^n} \frac{a^2}{h^2}\rho, \quad (19)$$

$$\max(E\epsilon_\phi) = \sigma_{\phi_0} - \frac{1}{m}\sigma_{x_0} \pm 2 \frac{b^n - \frac{1}{m^2}a^n}{a^n + b^n} \frac{b^2}{h^2}\rho. \quad (20)$$

These may be written as follows :

$$\max E_{\epsilon_x} = \sigma_{x_0} - \frac{1}{m} \sigma_{\phi_0} \pm 2 \frac{1 - \frac{1}{m^2} \left(\frac{b}{a}\right)^n}{1 + \left(\frac{b}{a}\right)^n} \frac{a^2}{h^2} p, \quad (21)$$

$$\max E_{\epsilon_\phi} = \sigma_{\phi_0} - \frac{1}{m} \sigma_{x_0} \pm 2 \frac{1 - \frac{1}{m^2} \left(\frac{a}{b}\right)^n}{1 + \left(\frac{a}{b}\right)^n} \frac{b^2}{h^2} p. \quad (22)$$

We have also, by substituting for  $E$  and  $F$  their values in equation (18),

$$z = \frac{p}{2Eh^3} \left\{ \frac{a^n - \frac{1}{m^2} b^n}{a^n + b^n} (a^2 - x^2)^2 + \frac{b^n - \frac{1}{m^2} a^n}{a^n + b^n} (b^2 - \phi^2)^2 \right\}. \quad (23)$$

In these results the exponent  $n$  is undetermined, and we have no means of determining it in the general case. We only know, that, since the deflection must increase for a decrease in  $x$  and  $\phi$ , therefore we must have, whenever  $a > b$ ,

$$\left(\frac{a}{b}\right)^n < m^2 \quad \therefore n < \frac{2 \log m}{\log \left(\frac{a}{b}\right)}.$$

This leaves the general case indeterminate; but a common practical case is not subject to this indetermination, i.e., the case when  $a = b$ , for then

$$\left(\frac{a}{b}\right)^n = \left(\frac{b}{a}\right)^n = 1,$$

whatever the value of  $n$ ; and hence equations (21), (22), and (23) give.

$$\max (E_{\epsilon_x}) = \sigma_{x_0} - \frac{1}{m} \sigma_{\phi_0} \pm \frac{m^2 - 1}{m^2} \frac{a^2}{h^2} p, \quad (24)$$

$$\max E_{\epsilon_\phi} = \sigma_{\phi_0} - \frac{1}{m} \sigma_{x_0} \pm \frac{m^2 - 1}{m^2} \frac{a^2}{h^2} p, \quad (25)$$

$$z = \frac{m^2 - 1}{m^2} \frac{p}{4Eh^3} \{ (a^2 - x^2)^2 + (a^2 - \phi^2)^2 \}, \quad (26)$$

and

$$\max z = \frac{m^2 - 1}{m^2} \frac{a^4}{2Eh^3} p. \quad (27)$$

#### FORMULÆ FOR THE SHEETS OF A LOCOMOTIVE FIRE-BOX.

In this case we have  $a = b$ ; hence (24), (25), and (27) apply: and if we write, with Grashof,  $m = 3$ , they become

$$\max (E\epsilon_x) = \sigma_{x_0} - \frac{1}{3} \sigma_{\phi_0} + \frac{8}{9} \frac{a^2}{h^2} p, \quad (28)$$

$$\max (E\epsilon_\phi) = \sigma_{\phi_0} - \frac{1}{3} \sigma_{x_0} + \frac{8}{9} \frac{a^2}{h^2} p, \quad (39)$$

$$\max (z) = \frac{4}{9} \frac{pa^4}{Eh^3}. \quad (30)$$

Now, in the case of the horizontal sheets,  $\sigma_{x_0} = \sigma_{\phi_0} = 0$ , and we have

$$\max (E\epsilon_x) = \frac{8}{9} \frac{a^2}{h^2} p, \quad (31)$$

$$\max (z) = \frac{4}{9} \frac{pa^4}{Eh^3}. \quad (32)$$

In the case of the vertical walls, inasmuch as these have to resist the steam-pressure in a vertical direction, the inner one is called upon to bear compression, and the outer tension, in a vertical direction. If  $l$  is the length of the outside of the fire-box, and  $l_1$  its breadth, we shall have for the outer plate, taking axis of  $x$  vertical,

$$\sigma_x = \frac{12p}{2(l + l_1)h}, \quad \sigma_{\phi_0} = 0;$$

and for the inner plate, if  $l$  and  $l_1'$  are corresponding dimensions of inside of fire-box,

$$\sigma_{x_0} = \frac{U_1 p}{2(l' + l_1')h}, \quad \sigma_{\phi_0} = 0.$$

And, by making these substitutions in (28), (29), and (30), we obtain our formulæ.

#### RECTANGULAR PLATE FIXED AT THE EDGES.

For this case Grashof deduces the equation of the middle layer as follows:—

1°. This equation must be a function of  $x$  and  $\phi$ .

2°. If  $2a$  and  $2b$  are the sides of the plate, this function must become

(a) When  $b = \infty$  for all values of  $\phi$ ,

$$s = \frac{p}{2Eh^3}(a^2 - x^2)^2.$$

(β) When  $a = \infty$  for all values of  $x$ ,

$$s = \frac{p}{2Eh^3}(b^2 - \phi^2)^2,$$

because the plate then becomes a beam fixed at the ends.

The function that will satisfy these two conditions is

$$s = \frac{p}{2Eh^3} \frac{(a^2 - x^2)^2(b^2 - \phi^2)^2}{a^4 + b^4}. \quad (1)$$

From this he deduces for max  $s$ , when  $x = \phi = 0$ ,

$$\max s = \frac{1}{2} \frac{p}{Eh^3} \frac{a^4 b^4}{a^4 + b^4}. \quad (2)$$

From (1) he deduces

$$\frac{d^2z}{dx^2} = -\frac{2p}{Eh^3} \frac{(a^2 - 3x^2)(b^2 - \phi^2)^2}{a^4 + b^4}, \quad (3)$$

$$\frac{d^2z}{d\phi^2} = -\frac{2p}{Eh^3} \frac{(a^2 - x^2)^2(b^2 - 3\phi^2)}{a^4 + b^4}, \quad (4)$$

$$\frac{d^2z}{dx d\phi} = \frac{8p}{Eh^3} \frac{(a^2 - x^2)x(b^2 - \phi^2)\phi}{a^4 + b^4}, \quad (5)$$

$$\max \frac{d^2z}{dx^2} = \frac{4p}{Eh^3} \frac{a^2 b^4}{a^4 + b^4}, \quad \text{for } x = \pm a, \phi = 0, \quad (6)$$

$$\max \frac{d^2z}{d\phi^2} = \frac{4p}{Eh^3} \frac{a^4 b^2}{a^4 + b^4}, \quad \text{for } \phi = \pm b, x = 0, \quad (7)$$

$$\max \frac{d^2z}{dx d\phi} = \frac{32}{27} \frac{p}{Eh^3} \frac{a^3 b^3}{a^4 + b^4}, \quad \text{for } x^2 = \frac{1}{3}a^2, \phi^2 = \frac{1}{3}b^2, \quad (8)$$

these corresponding to the points of inflection of a loaded beam fixed at the ends.

Hence (1), (2), and (5) of § 300 give

$$\max E\epsilon_x = \sigma_{x_0} - \frac{1}{m}\sigma_{\phi_0} \pm \frac{2b^4}{a^4 + b^4} \frac{a^2}{h^2} p, \quad (9)$$

$$\max (E\epsilon_\phi) = \sigma_{\phi_0} - \frac{1}{m}\sigma_{x_0} \pm \frac{2a^4}{a^4 + b^4} \frac{b^2}{h^2} p, \quad (10)$$

$$\max (\tau_s) = \frac{8}{27} \frac{m}{m+1} \frac{2a^2 b^2}{a^4 + b^4} \frac{ab}{h^2} p. \quad (11)$$

At the places where  $\epsilon_x$  and  $\epsilon_\phi$  are greatest,

$$\tau_s = 0.$$

At the place where  $\tau_s$  is greatest,

$$\sigma_x = \sigma_{x_0}, \quad \sigma_\phi = \sigma_{\phi_0}.$$

Hence it is either (9) or (10) that gives us the suitable formula to use in any special case.

EXAMPLES OF THEORY OF ELASTICITY.

1. It has been sometimes proposed to use oblique seams in a boiler-shell. Assume the seams at an angle of  $45^\circ$  with the axis of the boiler, a pressure of 100 lbs. per square inch of the steam, and a diameter of 4 feet. Find the tension per inch of length of seam, and its direction.

2. Given a shaft carrying 80 *HP*, and running at 250 revolutions per minute. Suppose the driving-pulley to be at the middle of the length, this being 6 feet, and given that the ratio of the tension on the tight side of the belt to that on the loose side is 3.75. Find the proper size of shaft, assuming 10000 lbs. per square inch as the working-strength of the iron.

3. What should be the thickness of a flat plate to bear 150 lbs. pressure per square inch, and stayed at points forming squares 8 inches on a side, the plate being of wrought-iron, working-strength 10000 lbs. per square inch.

4. Find inner radius of a hydraulic press to bear 1500 lbs. per square inch, given outer radius = 18 inches; material, cast-iron; tensile strength 20000 lbs. per square inch.
